Authority

56 This publication has been developed by NIST in accordance with its statutory responsibilities under the
57 Federal Information Security Modernization Act (FISMA) of 2014, 44 U.S.C. § 3551 *et seq.*, Public Law
58 (P.L.) 113-283. NIST is responsible for developing information security standards and guidelines, including
59 minimum requirements for federal information systems, but such standards and guidelines shall not apply
60 to national security systems without the express approval of appropriate federal officials exercising policy
61 authority over such systems. This guideline is consistent with the requirements of the Office of Management
62 and Budget (OMB) Circular A-130, Section 8b(3), *Securing Agency Information Systems*, as analyzed in
63 Circular A-130, Appendix IV: *Analysis of Key Sections*. Supplemental information is provided in Circular
64 A-130, Appendix III, *Security of Federal Automated Information Resources*.

65 Nothing in this publication should be taken to contradict the standards and guidelines made mandatory and
66 binding on federal agencies by the Secretary of Commerce under statutory authority. Nor should these
67 guidelines be interpreted as altering or superseding the existing authorities of the Secretary of Commerce,
68 Director of the OMB, or any other federal official. This publication may be used by nongovernmental
69 organizations on a voluntary basis and is not subject to copyright in the United States. Attribution would,
70 however, be appreciated by NIST.

75 Certain commercial entities, equipment, or materials may be identified in this document in order to describe an
76 experimental procedure or concept adequately. Such identification is not intended to imply recommendation or
77 endorsement by NIST, nor is it intended to imply that the entities, materials, or equipment are necessarily the best
78 available for the purpose.

79 There may be references in this publication to other publications currently under development by NIST in accordance
80 with its assigned statutory responsibilities. The information in this publication, including concepts and methodologies,
81 may be used by federal agencies even before the completion of such companion publications. Thus, until each
82 publication is completed, current requirements, guidelines, and procedures, where they exist, remain operative. For
83 planning and transition purposes, federal agencies may wish to closely follow the development of these new
84 publications by NIST.

85 Organizations are encouraged to review all draft publications during public comment periods and provide feedback to
86 NIST. All NIST Computer Security Division publications, other than the ones noted above, are available at
87 <https://csrc.nist.gov/publications>.

Reports on Computer Systems Technology

96 The Information Technology Laboratory (ITL) at the National Institute of Standards and
97 Technology (NIST) promotes the U.S. economy and public welfare by providing technical
98 leadership for the Nation's measurement and standards infrastructure. ITL develops tests, test
99 methods, reference data, proof of concept implementations, and technical analyses to advance the
100 development and productive use of information technology. ITL's responsibilities include the
101 development of management, administrative, technical, and physical standards and guidelines for
102 the cost-effective security and privacy of other than national security-related information in federal
103 information systems. The Special Publication 800-series reports on ITL's research, guidelines, and
104 outreach efforts in information system security, and its collaborative activities with industry,
105 government, and academic organizations.

106

Abstract

107 This document gives recommendations and guidelines for enhancing trust in email. The primary
108 audience includes enterprise email administrators, information security specialists and network
109 managers. This guideline applies to federal IT systems and will also be useful for small or
110 medium sized organizations. Technologies recommended in support of core Simple Mail
111 Transfer Protocol (SMTP) and the Domain Name System (DNS) include mechanisms for
112 authenticating a sending domain: Sender Policy Framework (SPF), Domain Keys Identified Mail
113 (DKIM) and Domain based Message Authentication, Reporting and Conformance (DMARC).
114 Recommendations for email transmission security include Transport Layer Security (TLS) and
115 associated certificate authentication protocols. Recommendations for email content security
116 include the encryption and authentication of message content using S/MIME
117 (Secure/Multipurpose Internet Mail Extensions) and associated certificate and key distribution
118 protocols.

119

Keywords

120 Email; Simple Mail Transfer Protocol (SMTP); Transport Layer Security (TLS); Sender Policy
121 Framework (SPF); Domain Keys Identified Mail (DKIM); Domain based Message
122 Authentication, Reporting and Conformance (DMARC); Domain Name System (DNS)
123 Authentication of Named Entities (DANE); S/MIME; OpenPGP.

124

125

126

Note to Reviewers

127

128 This second comment period for Revision 1 is to allow for comments on a newly included
129 security recommendation dealing with mail confidentiality. This revision also includes more text
130 on new email security protocols currently undergoing specification and finalization as IETF
131 Draft Standards. Reviewers should pay particular attention to Sections 5.2 and 7.3, which has
132 newly added material.

133

Audience

134 This document gives recommendations and guidelines for enhancing trust in email. The primary
135 audience for these recommendations is enterprise email administrators, information security
136 specialists and network managers. While some of the guidelines in this document pertain to
137 federal IT systems and network policy, most of the document will be more general in nature and
138 could apply to any organization.

139 For most of this document, it will be assumed that the organization has some or all responsibility
140 for email and can configure or manage its own email and Domain Name System (DNS) systems.
141 Even if this is not the case, the guidelines and recommendations in this document may help in
142 education about email security and can be used to produce a set of requirements for a contracted
143 service.

144

Trademark Information

145 All registered trademarks belong to their respective organizations.

146 **Executive Summary**

147 This document gives recommendations and guidelines for enhancing trust in email. The primary
148 audience includes enterprise email administrators, information security specialists and network
149 managers. This guideline applies to federal IT systems and will also be useful for small or
150 medium sized organizations.

151 Email is a core application of computer networking and has been such since the early days of
152 Internet development. In those early days, networking was a collegial, research-oriented
153 enterprise. Security was not a consideration. The past forty years have seen diversity in
154 applications deployed on the Internet, and worldwide adoption of email by research
155 organizations, governments, militaries, businesses and individuals. At the same time there has
156 been an associated increase in (Internet-based) criminal and nuisance threats.

157 The Internet's underlying core email protocol, Simple Mail Transport Protocol (SMTP), was
158 adopted in 1982 and is still deployed and operated today. However, this protocol is susceptible to
159 a wide range of attacks including man-in-the-middle content modification and content
160 surveillance. The basic standards have been modified and augmented over the years with
161 adaptations that mitigate some of these threats. With spoofing protection, integrity protection,
162 encryption and authentication, properly implemented email systems can be regarded as
163 sufficiently secure for government, financial and medical communications.

164 NIST has been active in the development of email security guidelines for many years. The most
165 recent NIST guideline on secure email is NIST SP 800-45, Version 2 of February 2007,
166 *Guidelines on Electronic Mail Security*. The purpose of that document is:

167 “To recommend security practices for designing, implementing and operating email
168 systems on public and private networks,”

169 Those recommendations include practices for securing the environments around enterprise mail
170 servers and mail clients, and efforts to eliminate server and workstation compromise. This guide
171 complements SP800-45 by providing more up-to-date recommendations and guidance for email
172 digital signatures and encryption (via S/MIME), recommendations for protecting against
173 unwanted email (spam), and recommendations concerning other aspects of email system
174 deployment and configuration.

175 Following a description of the general email infrastructure and a threat analysis, these guidelines
176 cluster into techniques for authenticating a sending domain, techniques for assuring email
177 transmission security and those for assuring email content security. The bulk of the security
178 enhancements to email rely on records and keys stored in the Domain Name System (DNS) by
179 one party, and extracted from there by the other party. Increased reliance on the DNS is
180 permissible because of the recent security enhancements there, in particular the development and
181 widespread deployment of the DNS Security Extensions (DNSSEC) to provide source
182 authentication and integrity protection of DNS data.

183 The purpose of authenticating the sending domain is to guard against senders (both random and
184 malicious actors) from spoofing another's domain and initiating messages with bogus content,

185 and against malicious actors from modifying message contents in transit. Sender Policy
186 Framework (SPF) is the standardized way for a sending domain to identify and assert the
187 authorized mail senders for a given domain. Domain Keys Identified Mail (DKIM) is the
188 mechanism for eliminating the vulnerability of man-in-the-middle content modification by using
189 digital signatures generated from the sending mail server.

190 Domain based Message Authentication, Reporting and Conformance (DMARC) was conceived
191 to allow email senders to specify policy on how their mail should be handled, the types of
192 security reports that receivers can send back, and the frequency those reports should be sent.
193 Standardized handling of SPF and DKIM removes guesswork about whether a given message is
194 authentic, benefitting receivers by allowing more certainty in quarantining and rejecting
195 unauthorized mail. In particular, receivers compare the “From” address in the message to the
196 SPF and DKIM results, if present, and the DMARC policy in the DNS. The results are used to
197 determine how the mail should be handled. The receiver sends reports to the domain owner about
198 mail claiming to originate from their domain. These reports should illuminate the extent to which
199 unauthorized users are using the domain, and the proportion of mail received that is “good.”

200 Man-in-the-middle attacks can intercept cleartext email messages as they are transmitted hop-by-
201 hop between mail relays. Any bad actor, or organizationally privileged actor, can read such mail
202 as it travels from submission to delivery systems. Email message confidentiality can be assured
203 by encrypting traffic along the path. The Transport Layer Security Protocol (TLS) uses an
204 encrypted channel to protect message transfers from man-in-the-middle attacks. TLS relies on
205 the Public Key Infrastructure (PKI) system of X.509 certificates to carry exchange material and
206 provide information about the entity holding the certificate. These are usually generated by a
207 Certificate Authority (CA). The global CA ecosystem has in recent years become the subject to
208 attack, and has been successfully compromised more than once. One way to protect against CA
209 compromises is to use the DNS to allow domains to specify their intended certificates or vendor
210 CAs. Such uses of DNS require that the DNS itself be secured with DNSSEC. Correctly
211 configured deployment of TLS may not stop a passive eavesdropper from viewing encrypted
212 traffic, but does practically eliminate the chance of deciphering it.

213 Server to server transport layer encryption also assures the integrity of email in transit, but
214 senders and receivers who desire end-to-end assurance, (i.e. mailbox to mailbox) may wish to
215 implement end-to-end, message based authentication and confidentiality protections. The sender
216 may wish to digitally sign and/or encrypt the message content, and the receiver can authenticate
217 and/or decrypt the received message. Secure Multipurpose Internet Mail Extensions (S/MIME) is
218 the recommended protocol for email end-to-end authentication and confidentiality. This usage of
219 S/MIME is not common at the present time, but is recommended. Certificate distribution remains
220 a significant challenge when using S/MIME, especially the distribution of certificates between
221 organizations. Research is underway on protocols that will allow the DNS to be used as a
222 lightweight publication infrastructure for S/MIME certificates.

223 S/MIME is also useful for authenticating mass email mailings originating from mailboxes that
224 are not monitored, since the protocol uses PKI to authenticate digitally signed messages,
225 avoiding the necessity of distributing the sender’s public key certificate in advance. Encrypted
226 mass mailings are more problematic, as S/MIME senders need to possess the certificate of each
227 recipient if the sender wishes to send encrypted mail.

228 Email communications cannot be made trustworthy with a single package or application. It
229 involves incremental additions to basic subsystems, with each technology adapted to a particular
230 task. Some of the techniques use other protocols such as DNS to facilitate specific security
231 functions like domain authentication, content encryption and message originator authentication.
232 These can be implemented discretely or in aggregate, according to organizational needs.

390

391 **1 Introduction**

392 **1.1 What This Guide Covers**

393 This guide provides recommendations for deploying protocols and technologies that improve the
394 trustworthiness of email. These recommendations reduce the risk of spoofed email being used as
395 an attack vector and reduce the risk of email contents being disclosed to unauthorized parties.
396 These recommendations cover both the email sender and receiver.

397 Several of the protocols discussed in this guide use technologies beyond the core email protocols
398 and systems. These includes the Domain Name System (DNS), Public Key Infrastructure (PKI)
399 and other core Internet protocols. This guide discusses how these systems can be used to provide
400 security services for email.

401 **1.2 What This Guide Does Not Cover**

402 This guide views email as a service, and thus it does not discuss topics such as individual server
403 hardening, configuration and network planning. These topics are covered in NIST Special
404 Publication 800-45, Version 2 of February 2007, *Guidelines on Electronic Mail Security* [SP800-
405 45]. This guide should be viewed as a companion document to SP 800-45 that provides more
406 updated guidance and recommendations that covers multiple components. This guide attempts to
407 provide a holistic view of email and will only discuss individual system recommendations as
408 examples warrant.

409 Likewise, this guide does not give specific configuration details for email components. There are
410 a variety of hardware and software components that perform one or multiple email related tasks
411 and it would be impossible to list them all in one guide. This guide will discuss protocols and
412 configuration in an implementation neutral manner and administrators will need to consult their
413 system documentation on how to execute the guidance for their specific implementations.

414 **1.3 Document Structure**

415 The rest of the document is presented in the following manner:

- 416 • **Section 2:** Discusses the core email protocols and the main components such as Mail
417 Transfer Agents (MTA) and Mail User Agents (MUA), and cryptographic email formats.
418
- 419 • **Section 3:** Discusses the threats against an organization's email service such as phishing,
420 spam and denial of service (DoS).
421
- 422 • **Section 4:** Discusses the protocols and techniques a sending domain can use to
423 authenticate valid email senders for a given domain. This includes protocols such as
424 Sender Policy Framework (SPF), DomainKeys Identified Mail (DKIM) and Domain-
425 based Message and Reporting Conformance (DMARC).
426

- 427 • **Section 5:** Discusses server-to-server and end-to-end email authentication and
428 confidentiality of message contents. This includes email sent over Transport Layer
429 Security (TLS), Secure Multipurpose Internet Mail Extensions (S/MIME) and OpenPGP.
430
- 431 • **Section 6:** Discusses technologies to reduce unsolicited and (often) malicious email
432 messages sent to a domain.
433
- 434 • **Section 7:** Discusses email security as it relates to end users and the final hop between
435 local mail delivery servers and email clients. This includes Internet Message Access
436 Protocol (IMAP), Post Office Protocol (POP3), and techniques for email encryption.
437

438 **1.4 Conventions Used in this Guide**

439 Throughout this guide, the following format conventions are used to denote special use text:

440 **keyword** - The text relates to a protocol keyword or text used as an example.

441 **Security Recommendation:** - Denotes a recommendation that administrators should note
442 and account for when deploying the given protocol or security feature.

443 URLs are also included in the text and references to guide readers to a given website or online
444 tool designed to aid administrators. This is not meant to be an endorsement of the website or any
445 product/service offered by the website publisher. All URLs were considered valid at the time of
446 writing.

447 2 Elements of Email

448 2.1 Email Components

449 There are a number of software components used to produce, send and transfer email. These
 450 components can be classified as clients or servers, although some components act as both. Some
 451 components are used interactively, and some are completely automated. In addition to the core
 452 components, some organizations use special purpose components that provide a specific set of
 453 security features. There are also other components used by mail servers when performing
 454 operations. These include the Domain Name System (DNS) and other network infrastructure
 455 pieces.

456 Fig 2-1 shows the relationship between the email system components on a network, which are
 457 described below in greater detail.

458

459

Fig 2-1: Main Components Used for Email

460 2.1.1 Mail User Agents (MUAs)

461 Most end users interact with their email system via a Mail User Agent (MUA). A MUA is a
 462 software component (or web interface) that allows an end user to compose and send messages
 463 and to one or more recipients. A MUA transmits new messages to a server for further processing
 464 (either final delivery or transfer to another server). The MUA is also the component used by end
 465 users to access a mailbox where in-bound emails have been delivered. MUAs are available for a
 466 variety of systems including mobile hosts. The proper secure configuration for an MUA depends
 467 on the MUA in question and the system it is running on. Some basic recommendations can be
 468 found in Section 7.

469 MUAs may utilize several protocols to connect to and communicate with email servers, (see
 470 Section 2.3.2 below). There may also be other features as well such as a cryptographic interface
 471 for producing encrypted and/or digitally signed email.

472 **2.1.2 Mail Transfer Agents (MTAs)**

473 Email is transmitted, in a “store and forward” fashion, across networks via Mail Transfer Agents
474 (MTAs). MTAs communicate using the Simple Mail Transfer Protocol (SMTP) described below
475 and act as both client and server, depending on the situation. For example, an MTA can act as a
476 server when accepting an email message from an end user's MUA, then act as a client in
477 connecting to and transferring the message to the recipient domain's MTA for final delivery.

478 MTAs can be described with more specialized language that denotes specific functions:

- 479 • **Mail Submission Agents (MSA):** An MTA that accepts mail from MUAs and begins the
480 transmission process by sending it to a MTA for further processing. Often the MSA and
481 first-hop MTA is the same process, just fulfilling both roles.
482
- 483 • **Mail Delivery Agent (MDA):** An MTA that receives mail from an organization's
484 inbound MTA and ultimately places the message in a specific mailbox. Like the MSA,
485 the MDA could be a combined in-bound MTA and MDA component.
486

487 Mail servers may also perform various security functions to prevent malicious email from being
488 delivered or include authentication credentials such as digital signatures (see Sender Policy
489 Framework Section 4.5 and DomainKeys Identified Mail (DKIM) Section 4.3). These security
490 functions may be provided by other components that act as lightweight MTAs or these functions
491 may be added to MTAs via filters or patches.

492 An email message may pass through multiple MTAs before reaching the final recipient. Each
493 MTA in the chain may have its own security policy (which may be uniform within an
494 organization, but may not be uniform) and there is currently no way for a sender to request a
495 particular level of security for the email message.

496 **2.1.3 Special Use Components**

497 In addition to MUAs and MTAs, an organization may use one or more special purpose
498 components for a particular task. These components may provide a security function such as
499 malware filtering, or may provide some business process functionality such as email archiving or
500 content filtering. These components may exchange messages with other parts of the email
501 infrastructure using all or part of the Simple Mail Transfer Protocol (see below) or use another
502 protocol altogether.

503 Given the variety of components, there is no one single set of configurations for an administrator
504 to deploy, and different organizations have deployed very different email architectures. An
505 administrator should consult the documentation for their given component and their existing site-
506 specific architecture.

507 **2.1.4 Special Considerations for Cloud and Hosted Service Customers**

508 Organizations that outsource their email service (whole or in part) may not have direct access to
509 MTAs or any possible special use components. In cases of Email as a Service (EaaS), the service

510 provider is responsible for the email infrastructure. Customers of Infrastructure as a Service
511 (IaaS) may have sufficient access privileges to configure their email servers themselves. In either
512 architecture, the enterprise may have complete configuration control over MUAs in use.

513 **2.1.5 Email Server and Related Component Architecture**

514 How an organization architects its email infrastructure is beyond the scope of this document. It is
515 up to the organization and administrators to identify key requirements (availability, security, etc.)
516 and available product or service offerings to meet those requirements. Federal IT administrators
517 also need to take relevant federal IT policies into account when acquiring and deploying email
518 systems.

519 Guidance for deploying and configuring a MTA for federal agency use exists as NIST SP 800-45
520 "Guidelines on Electronic Mail Security" [SP800-45]. In addition, the Dept. of Homeland
521 Security (DHS) has produced the "Email Gateway Reference Architecture" [REFARCH] for
522 agencies to use as a guide when setting up or modifying the email infrastructure for an agency.

523 **2.2 Related Components**

524 In addition to MUAs and MTAs, there are other network components used to support the email
525 service for an organization. Most obviously is the physical infrastructure: the cables, wireless
526 access points, routers and switches that make up the network. In addition, there are network
527 components used by email components in the process of completing their tasks. This includes the
528 Domain Name System, Public Key Infrastructure, and network security components that are used
529 by the organization.

530 **2.2.1 Domain Name System**

531 The Domain Name System (DNS) is a global, distributed database and associated lookup
532 protocol. DNS is used to map a piece of information (most commonly a domain name) to an IP
533 address used by a computer system. The DNS is used by MUAs to find MSAs and MTAs to find
534 the IP address of the next-hop server for mail delivery. Sending MTAs query DNS for the Mail
535 Exchange Resource Record (MX RR) of the recipient's domain (the part of an email address to
536 the right of the "@" symbol) in order to find the receiving MTA to contact.

537 In addition to the "forward" DNS (translate domain names to IP addresses or other data), there is
538 also the "reverse" DNS tree that is used to map IP addresses to their corresponding DNS name,
539 or other data. Traditionally, the reverse tree is used to obtain the domain name for a given client
540 based on the source IP address of the connection, but it is also used as a crude, highly imperfect
541 authentication check. A host compares the forward and reverse DNS trees to check that the
542 remote connection is likely valid and not a potential attacker abusing a valid IP address block.
543 This can be more problematic in IPv6, where even small networks can be assigned very large
544 address blocks. Email anti-abuse consortiums recommend that enterprises should make sure that
545 DNS reverse trees identify the authoritative mail servers for a domain [M3AAWG].

546 The DNS is also used as the publication method for protocols designed to protect email and
547 combat malicious, spoofed email. Technologies such as Sender Policy Framework (SPF),
548 DomainKeys Identified Mail (DKIM) and other use the DNS to publish policy artifacts or public

549 keys that can be used by receiving MTAs to validate that a given message originated from the
550 purported sending domain's mail servers. These protocols are discussed in Section 4. In addition,
551 there are new proposals to encode end-user certificates (for S/MIME or OpenPGP) in the DNS
552 using a mailbox as the hostname. These protocols are discussed in Section 5.3.

553 A third use of the DNS with email is with reputation services. These services provide information
554 about the authenticity of an email based on the purported sending domain or originating IP
555 address. These services do not rely on the anti-spoofing techniques described above but through
556 historical monitoring, domain registration history, and other information sources. These services
557 are often used to combat unsolicited bulk email (i.e. spam) and malicious email that could
558 contain malware or links to subverted websites.

559 The Domain Name System Security Extensions (DNSSEC) [RFC4033] provides cryptographic
560 security for DNS queries. Without security, DNS can be subjected to a variety of spoofing and
561 man-in-the-middle attacks. Recommendations for deploying DNS in a secure manner are beyond
562 the scope of this document. Readers are directed to NIST SP 800-81 [SP800-81] for
563 recommendations on deploying DNSSEC.

564 **2.2.2 Enterprise Perimeter Security Components**

565 Organizations may utilize security components that do not directly handle email, but may
566 perform operations that affect email transactions. These include network components like
567 firewalls, Intrusion Detection Systems (IDS) and similar malware scanners. These systems may
568 not play any direct role in the sending and delivering of email but may have a significant impact
569 if misconfigured. This could result in legitimate SMTP connections being denied and the failure
570 of valid email to be delivered. Network administrators should take the presence of these systems
571 into consideration when making changes to an organization's email infrastructure. This document
572 makes no specific recommendations regarding these peripheral components.

573 **2.2.3 Public Key Infrastructure (PKIX)**

574 Organizations that send and receive S/MIME or OpenPGP protected messages, as well as those
575 that use TLS, will also need to rely on the certificate infrastructure used with these protocols. The
576 certificate infrastructure does not always require the deployment of a dedicated system, but does
577 require administrator time to obtain, configure and distribute security credentials to end-users.

578 X.509 certificates can be used to authenticate one (or both) ends of a TLS connection when
579 SMTP runs over TLS (usually MUA to MTA). S/MIME also uses X.509 certificates [RFC5280]
580 to certify and store public keys used to validate digital signatures and encrypt email. The Internet
581 X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile is
582 commonly called PKIX and is specified by [RFC5280]. Certificate Authorities (CA) (or the
583 organization itself) issues X.509 certificates for an individual end-user or enterprise/business role
584 (performed by a person or not) that sends email (for S/MIME). Recommendations for S/MIME
585 protected email are given in Section 5. Recommendations for SMTP over TLS are given in
586 Section 5. Federal agency network administrators should also consult NIST SP 800-57 Part 3
587 [SP800-57P3] for further guidance on cryptographic parameters and deployment of any PKI
588 components and credentials within an organization.

589 2.3 Email protocols

590 There are two types of protocols used in the transmission of email. The first are the protocols
591 used to transfer messages between MTAs and their end users (using MUAs). The second is the
592 protocol used to transfer messages between mail servers.

593 This guide is not meant to be an in-depth discussion of the protocols used in email. These
594 protocols are discussed here simply for background information.

595 2.3.1 Simple Mail Transfer Protocol (SMTP)

596 Email messages are transferred from one mail server to another (or from an MUA to
597 MSA/MTA) using the Simple Mail Transfer Protocol (SMTP). SMTP was originally specified in
598 1982 in [RFC 821] and has undergone several revisions, the most current being [RFC5321].
599 SMTP is a text-based client-server protocol where the client (email sender) contacts the server
600 (next-hop MTA) and issues a set of commands to tell the server about the message to be sent,
601 and then transmits the message itself. The majority of these commands are ASCII text messages
602 sent by the client and a resulting return code (also ASCII text) returned by the server. The basic
603 SMTP connection procedure is shown below in Fig 2-2:

```

604 Client connects to port 25
605 Server: 220 mx.example.com
606 Client: HELO mta.example.net
607 S: 250 Hello mta.example.net, I am glad to meet you
608 C: MAIL FROM:<alice@example.org>
609 S: 250 Ok
610 C: RCPT TO:<bob@example.com>
611 S: 354 End data with <CR><LF>.<CR><LF>
612 Client sends message headers and body
613 C: .
614 S: 250 Ok: queued as 12345
615 C: QUIT
616 S: 221 Bye
617 Server closes the connection

```

618 **Fig 2-2: Basic SMTP Connection Set-up**

619 In the above, the client initiates the connection using TCP over port 25¹. After the initial
620 connection, the client and server perform a series of SMTP transactions to send the message.
621 These transactions take the form of first stating the return address of the message (known as the
622 return path) using the **MAIL** command, then the recipient(s) using the **RCPT** command and
623 ending with the **DATA** command which contains the header and body of the email message.
624 After each command the server responds with either a positive or negative (i.e. error) code.

¹ Although MUAs often use TCP port 587 when submitting email to be sent.

625 SMTP servers can advertise the availability of options during the initial connection. These
626 extensions are currently defined in [RFC5321]. These options usually deal with the transfer of the
627 actual message and will not be covered in this guide except for the STARTTLS option. This
628 option advertised by the server is used to indicate to the client that Transport Layer Security
629 (TLS) is available. SMTP over TLS allows the email message to be sent over an encrypted
630 channel to protect against monitoring a message in transit. Recommendations for configuring
631 SMTP over TLS are given in Section 5.2.

632 **2.3.2 Mail Access Protocols (POP3, IMAP, MAPI/RPC)**

633 MUAs typically do not use SMTP when retrieving mail from an end-user's mailbox. MUAs use
634 another client-server protocol to retrieve the mail from a server for display on an end-user's host
635 system. These protocols are commonly called Mail Access Protocols and are either Post Office
636 Protocol (POP3) or Internet Message Access Protocol (IMAP). Most modern MUAs support
637 both protocols but an enterprise service may restrict the use of one in favor of a single protocol
638 for ease of administration or other reasons. Recommendations for the secure configuration of
639 these protocols are given in Section 7.

640 POP version 3 (POP3) [STD35] is the simpler of the two protocols and typically downloads all
641 mail for a user from the server, then deletes the copy on the server, although there is an option to
642 maintain it on the server. POP3 is similar to SMTP, in that the client connects to a port (normally
643 port 110 or port 995 when using TLS) and sends ASCII commands, to which the server
644 responds. When the session is complete, the client terminates the connection. POP3 transactions
645 are normally done in the clear, but an extension is available to do POP3 over TLS using the
646 STLS command, which is very similar to the STARTTLS option in SMTP. Clients may connect
647 initially over port 110 and invoke the STLS command, or alternatively, most servers allow TLS
648 by default connections on port 995.

649 IMAP [RFC3501] is an alternative to POP3 but includes more built-in features that make it more
650 appealing for enterprise use. IMAP clients can download email messages, but the messages
651 remain on the server. This and the fact that multiple clients can access the same mailbox
652 simultaneously mean that end-users with multiple devices (laptop and smartphone for example),
653 can keep their email synchronized across multiple devices. Like POP3, IMAP also has the ability
654 to secure the connection between a client and a server. Traditionally, IMAP uses port 143 with
655 no encryption. Encrypted IMAP runs over port 993, although modern IMAP servers also support
656 the STARTTLS option on port 143.

657 In addition to POP3 and IMAP, there are other proprietary protocols in use with certain
658 enterprise email implementations. Microsoft Exchange clients² can use the Messaging
659 Application Programming Interface (MAPI/RPC) to access a mailbox on a Microsoft Exchange
660 server (and some other compatible implementations). Some cloud providers require clients to
661 access their cloud-based mailbox using a web portal as the MUA instead of a dedicated email
662 client. With the exception of Microsoft's Outlook Web Access, most web portals use IMAP to

² Administrators should consult their implementation's version-specific documentation on the correct security configuration.

663 access the user's mailbox.

664 2.3.3 Internet Email Addresses

665 Two distinct email addresses are used when sending an email via SMTP: the SMTP MAIL
666 FROM address and the email header FROM address. The SMTP envelope MAIL FROM (also
667 sometimes referred to as the *RFC5321.From*, or the *return-path* address, or *envelope From:*) is
668 from address used in the client SMTP **mail from:** command as shown in Fig. 2-2 above. This
669 email address may be altered by a sending MTA and may not always match the email address of
670 the original sender. In the rest of this document, the term *envelope-From:* will be used. The
671 second is the sender email address (sometimes referred to as the *RFC5322.From*). This is the
672 address end-users see in the message header. In the rest of this document, the term *message-*
673 *From:* will be used to denote this email address. The full details of the syntax and semantics of
674 email addresses are defined in [RFC3696], [RFC5321] and [RFC5322].

675 Both types of contemporary email addresses consist of a local-part separated from a domain-part
676 (a fully-qualified domain name) by an at-sign ("@") (e.g., **local-part@domain-part**). Typically,
677 the local-part identifies a user of the mail system or server identified by the domain-part. The
678 semantics of the local-part are not standardized, which occasionally causes confusion among
679 both users and developers.³ The domain-part is typically a fully qualified domain name of the
680 system or service that hosts the user account that is identified by the local-part (e.g.,
681 **user@example.com**).

682 While the **user@example.com** is by far the most widely used form of email address, other forms
683 of addresses are sometimes used. For example, the local-part may include "sub-addressing" that
684 typically specifies a specific mailbox/folder within a user account (e.g.,
685 **user+folder@example.com**). Exactly how such local-parts are interpreted can vary across specific
686 mail system implementations. The domain-part can refer to a specific MTA server, the domain of
687 a specific enterprise or email service provider (ESP).

688 The remainder of this document will use the terms *email-address*, *local-part* and *domain-part* to
689 refer the Internet email addresses and their component parts.

690 2.4 Email Formats

691 Email messages may be formatted as plain text or as compound documents containing one or
692 more components and attachments. Modern email systems layer security mechanisms on top of
693 these underlying systems.

694 2.4.1 Email Message Format: Multi-Purpose Internet Mail Extensions (MIME)

695 Internet email was originally sent as plain text ASCII messages [RFC2822]. The Multi-purpose
696 Internet Mail Extensions (MIME) [RFC2045] [RFC2046] [RFC2047] allows email to contain
697 non-ASCII character sets as well as other non-text message components and attachments.

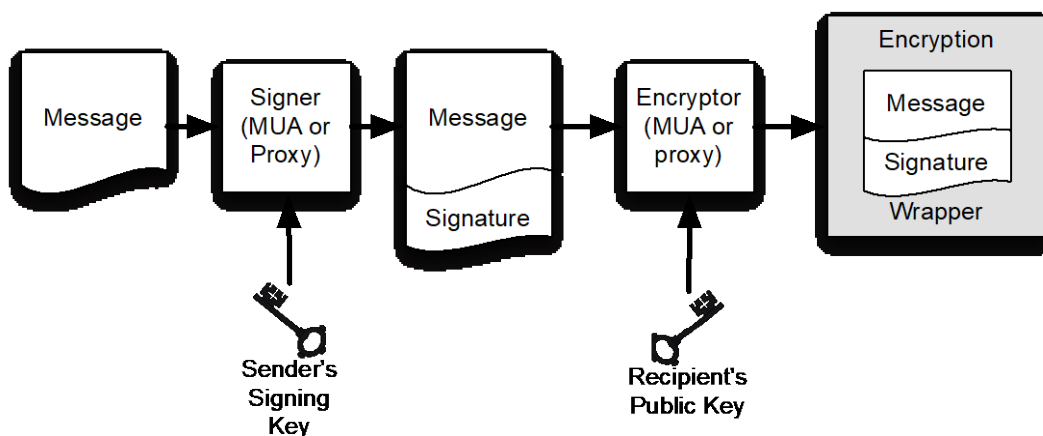

³ For example, on some systems the local-parts local-part, lo.cal-part, and local-part+special represent the same mailbox or users, while on other systems they are different.

698 Essentially MIME allows for an email message to be broken into parts, with each part identified
 699 by a content type. Typical content types include **text/plain** (for ASCII text), **image/jpeg**, **text/html**,
 700 etc. A mail message may contain multiple parts, which themselves may contain multiple parts,
 701 allowing MIME-formatted messages to be included as attachments in other MIME-formatted
 702 messages. The available types are listed in an IANA registry⁴ for developers, but not all may be
 703 understood by all MUAs.

704 2.4.2 Security in MIME Messages (S/MIME)

705 The Secure Multi-purpose Internet Mail Extensions (S/MIME) is a set of widely implemented
 706 proposed Internet standards for cryptographically securing email [RFC5750] [RFC5751].
 707 S/MIME provides authentication, integrity and non-repudiation (via digital signatures) and
 708 confidentiality (via encryption). S/MIME utilizes asymmetric keys for cryptography (i.e. public
 709 key cryptography) where the public portion is normally encoded and presented as X.509 digital
 710 certificates.

711 With S/MIME, signing digital signatures and message encryption are two distinct operations:
 712 messages can be digitally signed, encrypted, or both digitally signed *and* encrypted (Figure 2-5).
 713 Because the process is first to sign and then encrypt, S/MIME is vulnerable to re-encryption
 714 attacks⁵; a protection is to include the name of the intended recipient in the encrypted message.

715

716 **Figure 2-5: S/MIME Messages can be signed, encrypted, or both signed and encrypted**

717 2.4.3 Pretty Good Privacy (PGP/OpenPGP)

718 OpenPGP [RFC3156] [RFC4880] is an alternative proposed Internet standard for digitally
 719 signing and encrypting email. OpenPGP is an adaptation of the message format implemented by
 720 the Pretty Good Privacy (PGP) email encryption system that was first released in 1991. Whereas
 721 the PGP formats were never formally specified, OpenPGP specifies open, royalty-free formats

⁴ <http://www.iana.org/assignments/media-types/media-types.xhtml>

⁵ Don Davis. 2001. Defective Sign & Encrypt in S/MIME, PKCS#7, MOSS, PEM, PGP, and XML. In *Proceedings of the General Track: 2001 USENIX Annual Technical Conference*, Yoonho Park (Ed.). USENIX Association, Berkeley, CA, USA, 65-78.

722 for encryption keys, signatures, and messages. Today the most widely used implementation of
723 OpenPGP is Gnu Privacy Guard (gpg)⁶, an open source command-line program that runs on
724 many platforms, with APIs in popular languages such as C, Python and Perl. Most desktop and
725 web-based applications that allow users to send and receive OpenPGP-encrypted mail rely on
726 gpg as the actual cryptographic engine.

727 OpenPGP provides similar functionality as S/MIME, with three significant differences:

- 728 • **Key Certification:** Whereas X.509 certificates are issued by Certificate Authorities (or
729 local agencies that have been delegated authority by a CA to issue certificates), users
730 generate their own OpenPGP public and private keys and then solicit signatures for their
731 public keys from individuals or organizations to which they are known. Whereas X.509
732 certificates can be signed by a single party, OpenPGP public keys can be signed by any
733 number of parties. Whereas X.509 certificates are trusted if there is a valid PKIX chain to
734 a trusted root, an OpenPGP public key is trusted if it is signed by another OpenPGP
735 public key that is trusted by the recipient. This is called the “Web-of-Trust.”
736
- 737 • **Key Distribution:** OpenPGP does not always include the sender’s public key with each
738 message, so it may be necessary for recipients of OpenPGP-messages to separately obtain
739 the sender’s public key in order to verify the message or respond to the sender with an
740 encrypted message. Many organizations post OpenPGP keys on SSL-protected websites;
741 people who wish to verify digital signatures or send these organizations encrypted mail
742 need to manually download these keys and add them to their OpenPGP clients.
743 Essentially this approach exploits the X.509 certificate infrastructure to certify OpenPGP
744 keys, albeit with a process that requires manual downloading and verification.
745

746 OpenPGP keys may also be registered with the OpenPGP “public key servers” (described
747 below). OpenPGP “public key servers” are internet connected systems that maintain a
748 database of PGP public keys organized by email address. Anyone may post a public key
749 to the OpenPGP key servers, and that public key may contain any email address. Some
750 OpenPGP clients can search the key servers for all of the keys that belong to a given
751 email address and download the keys that match. Because there are no access controls on
752 the servers, attackers are free to submit a fraudulent certificate, and it is the responsibility
753 of the person or program that downloads the certificate to validate it.
754

- 755 • **Key and Certificate Revocation:** S/MIME keys are revoked using the PKIX revocation
756 infrastructure of Certificate Revocation Lists [RFC5280] and the Online Certificate Status
757 Protocol (OCSP) [RFC6960]. These protocols allow a certificate to be revoked at any
758 time by the CA. With OpenPGP, in contrast a key is only allowed to be revoked by the
759 key holder, and only with a Key Revocation Certificate. Thus, an OpenPGP user who
760 loses access to a private key has no way to revoke the key if a Key Revocation Certificate
761 was not prepared in advance. If a Key Revocation Certificate does exist, the certificate
762 can be uploaded to a PGP Key Server, OpenPGP key servers are *generally not checked*

⁶ <https://www.gnupg.org/>

763 by a client that already has a copy of an OpenPGP key. Thus, is it not clear how relying
 764 parties learn that an OpenPGP key has been revoked.

765 The Web-of-Trust is designed to minimize the problems of the key server. After an OpenPGP
 766 user downloads *all* of the keys associated with a particular email address, the correct OpenPGP
 767 certificate is selected by the signatures that it carries. Because Web-of-Trust supports arbitrary
 768 validation geometries, it allows both the top-down certification geometry of X.509 as well as
 769 peer-to-peer approaches. However, studies have demonstrated that users find this process
 770 confusing [WHITTEN1999], and the Web-of-Trust has not seen widespread adoption.

771 An alternative way to publish OpenPGP keys using the DNS is described in Section 5.3.2,
 772 OpenPGP, although the technique has not yet been widely adopted.

773 Like S/MIME, among the biggest hurdles of deploying OpenPGP are the need for users to create
 774 certificates in advance, the difficulty of obtaining the certificate of another user in order to send
 775 an encrypted message, and incorporating this seamlessly into mail clients. However, in
 776 OpenPGP this difficulty impacts both digital signatures and encryption, since OpenPGP
 777 messages may not include the sender’s certificate.

778 These differences are summarized in Table 2-1.

779 **Table 2-1: Comparison of S/MIME and OpenPGP operations**

Action	S/MIME	OpenPGP
Key creation	Users obtain X.509 certificates from employer (e.g. a US Government PIV card [FIPS 201]) or a Certificate Authority	Users make their own public/private key pairs and have them certified by associates.
Certificate Verification	PKIX: Certificates are verified using trusted roots that are installed on the end user’s computer.	Web-of-Trust: Keys can be signed by any number of certifiers. Users base their trust decisions on whether or not they “trust” the keys that were used to sign the key.
Certificate Revocation	Certificates can be revoked by the CA or Issuer. Methods exist to publish revoked status of key (e.g. Certificate Revocation List, etc.).	Certificates can only be revoked by the public key’s owner. Few options to signal key revocation and no uniform way for clients to see that a key has been revoked.
Obtaining public keys	Querying an LDAP server or exchanging digitally signed email messages.	PGP public key server or out-of-band mechanisms (e.g. posting a public key on a web page.)

780 **2.5 Secure Web-Mail Solutions**

781 Whereas S/MIME and OpenPGP provide a security overlay for traditional Internet email, some
782 organizations have adopted secure web-mail systems as an alternative approach for sending
783 encrypted e-mail messages between users. Secure web-mail systems can protect email messages
784 solely with host-based security, or they can implement a cryptographic layer using S/MIME,
785 OpenPGP, or other algorithms, such as the Boneh-Franklin (BF) and Boneh-Boyen (BB1)
786 Identity-Based Encryption (IBE) algorithms [RFC5091] [RFC5408] [RFC5409].

787 Secure webmail systems can perform message decryption at the web server or on the end-user's
788 client. In general, these systems are less secure than end-to-end systems because the private key
789 is under the control of the web server, which also has access to the encrypted message. These
790 systems cannot guarantee non-repudiation, since the server has direct access to the signing key.

791 An exception is webmail-based systems that employ client-side software to make use of a private
792 key stored at the client—for example, a webmail plug-in that allows the web browser to make
793 use of a private key stored in a FIPS-201 compliant smartcard. In these cases, the message is
794 decrypted and displayed at the client, and the server does not access the decrypted text of the
795 message.

796 **3 Security Threats to an Email Service**

797 The security threats to email service discussed in this section are related to canonical functions of
798 the service such as: message submission (at the sender end), message transmission (transfer) and
799 message delivery (at the recipient end).

800 Threats to the core email infrastructure functions can be classified as follows:

- 801 • **Integrity-related threats to the email system**, which could result in unauthorized access
802 to an enterprises' email system, or spoofed email used to initiate an attack.
- 803 • **Confidentiality-related threats to email**, which could result in unauthorized disclosure
804 of sensitive information.
- 805 • **Availability-related threats to the email system**, which could prevent end users from
806 being able to send or receive email.

807 The security threats due to insufficiency of core security functions are not covered. These include
808 threats to support infrastructure such as network components and firewalls, host OS and system
809 threats, and potential attacks due to lax security policy at the end user or administrator level (e.g.,
810 poor password choices). Threats directed to these components and recommendations for
811 enterprise security policies are found in other documents.

812 **3.1 Integrity-related Threats**

813 Integrity in the context of an email service assumes multiple dimensions. Each dimension can be
814 the source of one or more integrity-related threats:

- 815 • Unauthorized email senders within an organization's IP address block
- 816 • Unauthorized email receivers within an organization's IP address block
- 817 • Unauthorized email messages from a valid DNS domain
- 818 • Tampering/Modification of email content from a valid DNS domain
- 819 • DNS Cache Poisoning
- 820 • Phishing and spear phishing

821 **3.1.1 Unauthorized Email Senders within an organization's IP address block**

822 An unauthorized email sender is some MSA or MTA that sends email messages that appear to be
823 from a user in a specific domain (e.g. **user@example.com**), but is not identified as a legitimate
824 mail sender by the organization that runs the domain.

825 The main risk that an unauthorized email sender may pose to an enterprise is that a sender may
826 be sending malicious email and using the enterprise's IP address block and reputation to avoid
827 anti-spam filters. A related risk is that the sender may be sending emails that present themselves
828 as legitimate communications from the enterprise itself.

829 There are many scenarios that might result in an unauthorized email sender:

- 830 • Malware present on an employee's laptop may be sending out email without the
831 employee's knowledge.
- 832 • An employee (or intruder) may configure and operate a mail server without authorization.
- 833 • A device such as a photocopier or an embedded system may contain a mail sender that is
834 sending mail without anyone's knowledge.

835 One way to mitigate the risk of unauthorized senders is for the enterprise to block outbound port
836 25 (used by SMTP) for all hosts except those authorized to send mail. In addition, domains can
837 deploy the sender authentication mechanism described in Section 4.3 (Sender Policy Framework
838 (SPF)), using which senders can assert the IP addresses of the authorized MTAs for their domain
839 using a DNS Resource Record.

840 **Security Recommendation 3-1:** To mitigate the risk of unauthorized sender, an enterprise
841 administrator should block outbound port 25 (except for authorized mail senders) and look to
842 deploy firewall or intrusion detection systems (IDS) that can alert the administrator when an
843 unauthorized host is sending mail via SMTP to the Internet.

844 The proliferation of virtualization greatly increases the risk that an unauthorized virtual server
845 running on a virtual machines (VMs) within a particular enterprise might send email. This is
846 because many VMs are configured by default to run email servers (MTAs), and many VM
847 hypervisors use network address translation (NAT) to share a single IP address between multiple
848 VMs. Thus, a VM that is unauthorized to send email may share an IP address with a legitimate
849 email sender. To prevent such a situation, ensure that VMs that are authorized mail senders and
850 those VMs that are not authorized, do not share the same set of outbound IP addresses. An easy
851 way to do this is assigning these VMs to different NAT instances. Alternatively, internal firewall
852 rules can be used to block outbound port 25 for VMs that are not authorized to send outbound
853 email.

854 **Security Recommendation 3-2:** Systems that are not involved in the organization's email
855 infrastructure should be configured to not run Mail Transfer Agents (MTAs). Internal systems
856 that need to send mail should be configured to use a trusted internal MSA.

857 **3.1.2 Unauthorized Email Receiver within an Organization's IP Address Block**

858 Unauthorized mail receivers are a risk to the enterprise IT security posture because they may be
859 an entry point for malicious email. If the enterprise email administrator does not know of the
860 unauthorized email receiver, they cannot guarantee the server is secure and provides the
861 appropriate mail handling rules for the enterprise such as scanning for malicious links/code,
862 filtering spam, etc. This could allow malware to bypass the enterprise perimeter defenses and
863 enter the local network undetected.

864 **Security Recommendation 3-3:** To mitigate the risk of unauthorized receivers, an enterprise
865 administrator should block inbound port 25 and look to deploy firewall or intrusion detection
866 systems (IDS) that can alert the administrator when an unauthorized host is accepting mail via
867 SMTP from the Internet.

868 **3.1.3 Unauthorized Email Messages from a Valid DNS Domain (Address Spoofing)**

869 Just as organizations face the risk of unauthorized email senders, they also face the risk that they
870 might receive email from an unauthorized sender. This is sometimes called “spoofing,” especially
871 when one group or individual sends mail that appears to come from another. In a spoofing attack,
872 the adversary spoofs messages using another (sometimes even non-existent) user’s email
873 address.

874 For example, an attacker sends emails that purport to come from user@example.com, when in
875 fact the email messages are being sent from a compromised home router. Spoofing the message-
876 From: address is trivial, as the SMTP protocol [RFC2821] allows clients to set any message-
877 From: address. Alternatively, the adversary can simply configure a MUA with the name and
878 email address of the spoofed user and send emails to an open SMTP relay (see [RFC2505] for a
879 discussion of open relays).

880 The same malicious configuration activity can be used to configure and use wrong misleading or
881 malicious display names. When a display name that creates a degree of trust such as
882 “Administrator” shows up on the email received at the recipient’s end, it might make the
883 recipient reveal some sensitive information which the recipient would not normally do. Thus
884 the spoofing threat/attack also has a social engineering aspect dimension as well.

885 Section 4 discusses a variety of countermeasures for this type of threat. The first line of defense is
886 to deploy domain-based authentication mechanisms (see Section 4). These mechanisms can be
887 used to alert or block email that was sent using a spoofed domain. Another end-to-end
888 authentication technique is to use digital signatures to provide integrity for message content and
889 since the issue here is the email address of the sender, the digital signature used should cover the
890 header portion of the email message that contains the address of the sender.

891 **3.1.4 Tampering/Modification of Email Content**

892 The content of an email message, just like any other message content traveling over the Internet,
893 is liable to be altered in transit. Hence the content of the received email may not be the same as
894 what the sender originally composed. The countermeasure for this threat is for the sender to
895 digitally sign the message, attach the signature to the plaintext message and for the receiver to
896 verify the signature.

897 There are several solutions available to mitigate this risk by either encrypting the transmission of
898 email messages between servers using Transport Layer Security (TLS) for SMTP or using an
899 end-to-end solution to digitally sign email between initial sender and final receiver.
900 Recommendations for using TLS with SMTP are discussed in Section 5.2.1 and end-to-end
901 email encryption protocols are discussed in Section 4.6. The use of digital signatures within the
902 S/MIME and OpenPGP protocols is described in section 5.3.

903 **3.1.5 DNS Cache Poisoning**

904 Email systems rely on DNS for many functions. Some of them are:

- 905 • The sending MTA uses the DNS to find the IP address of the next-hop email server
906 (assuming the To: address is not a local mailbox).
- 907 • The recipient email server (if domain based email authentication is supported) uses the
908 DNS to look for appropriate records in the sending DNS domain either to authenticate the
909 sending email server (using SPF) or to authenticate an email message for its origin
910 domain (using DKIM). See Section 5 for details domain based authentication
911 mechanisms.

912 There are risks to using the DNS as a publication mechanism for authenticating email. First,
913 those highly motivated to conduct phishing/spam campaigns, may attempt to spoof a given
914 domain's DNS-based email authentication mechanisms in order to continue to deliver spoofed
915 email masquerading as the domain in question. The second risk is that an attacker would spoof a
916 domain's DNS-based authentication mechanisms in order to disrupt legitimate email from the
917 source domain. For example, maliciously spoofing the SPF record of authorized mail relays, to
918 exclude the domains legitimate MTAs, could result in all legitimate email from the target domain
919 being dropped by other MTAs. Lastly, a resolver whose cache has been poisoned can potentially
920 return the IP address desired by an attacker, rather than the legitimate IP address of a queried
921 domain name. In theory, this allows email messages to be redirected or intercepted.

922 Another impact of a DNS server with a poisoned cache as well as a compromised web server is
923 that the users are redirected to a malicious server/address when attempting to visit a legitimate
924 web site. If this phenomenon occurs due to a compromised web server, it is termed as *pharming*.
925 Although the visit to a legitimate web site can occur by clicking on a link in a received email,
926 this use case has no direct relevance to integrity of an email service and hence is outside the
927 scope of this document.

928 As far as DNS cache poisoning is concerned, DNSSEC security extension [RFC4033]
929 [RFC4034] [RFC4035] can provide protection from these kind of attacks since it ensures the
930 integrity of DNS resolution through an authentication chain from the root to the target domain of
931 the original DNS query. However, even the presence of a single non-DNSSEC aware server in
932 the chain can compromise the integrity of the DNS resolution.

933 **3.1.6 Phishing and Spear Phishing**

934 *Phishing* is the process of illegal collection of private/sensitive information using a spoofed
935 email as the means. This is done with the intention of committing identity theft, gaining access to
936 credit cards and bank accounts of the victim etc. Adversaries use a variety of tactics to make the
937 recipient of the email into believing that they have received the phishing email from a legitimate
938 user or a legitimate domain, including:

- 939 • Using a message-From: address that looks very close to one of the legitimate addresses
940 the user is familiar with or from someone claiming to be an authority (IT administrator,
941 manager, etc.).

- 942 • Using the email’s content to present to the recipient an alarm, a financial lure, or
943 otherwise attractive situation, that either makes the recipient panic or tempts the recipient
944 into taking an action or providing requested information.
- 945 • Sending the email from an email using a legitimate account holder’s software or
946 credentials, typically using a bot that has taken control of the email client or malware that
947 has stolen the user’s credentials (described in detail in Section 3.3.1 below)

948 As part of the email message, the recipient may usually be asked to click on a link to what
949 appears like a legitimate website, but in fact is a URL that will take the recipient into a spoofed
950 website set up by the adversary. If the recipient clicks on the embedded URL, the victim often
951 finds that the sign-in page, logos and graphics are identical to the legitimate website in the
952 adversary-controlled website, thereby creating the trust necessary to make the recipient submit
953 the required information such as user ID and the password. Some attackers use web pages to
954 deliver malware directly to the victim’s web browser.

955 In many instances, the phishing emails are generated in thousands without focus on profile of the
956 victims. Hence they will have a generic greeting such as “Dear Member”, “Dear Customer” etc.
957 A variant of phishing is *spear phishing* where the adversary is aware of, and specific about, the
958 victim’s profile. More than a generic phishing email, a spear phishing email makes use of more
959 context information to make users believe that they are interacting with a legitimate source. For
960 example, a spear phishing email may appear to relate to some specific item of personal
961 importance or a relevant matter at the organization –for instance, discussing payroll
962 discrepancies or a legal matter. As in phishing, the ultimate motive is the same – to lure the
963 recipient to an adversary-controlled website masquerading as a legitimate website to collect
964 sensitive information about the victim or attack the victim’s computer.

965 There are two minor variations of phishing: *clone phishing* and *whaling*. Clone phishing is the
966 process of cloning an email from a legitimate user carrying an attachment or link and then
967 replacing the link or attachment alone with a malicious version and then sending altered email
968 from an email address spoofed to appear to come from the original sender (carrying the pretext
969 of re-sending or sending an updated version). Whaling is a type of phishing specifically targeted
970 against high profile targets so that the resulting damage carries more publicity and/or financial
971 rewards for the perpetrator is more.

972 The most common countermeasures used against phishing are domain-based checks such as SPF,
973 DKIM and DMARC (see Section 4). More elaborate is to design anti-phishing filters that can
974 detect text commonly used in phishing emails, recovering hidden text in images, intelligent word
975 recognition – detecting cursive, hand-written, rotated or distorted texts as well as the ability to
976 detect texts on colored backgrounds. While these techniques will not prevent malicious email
977 sent using compromised legitimate accounts, they can be used to reduce malicious email sent
978 from spoofed domains or spoofed “From:” addresses.

979 **3.2 Confidentiality-related Threats**

980 A confidentiality-related threat occurs when the data stream containing email messages with
981 sensitive information are accessible to an adversary. The type of attack that underlies this threat

982 can be passive since the adversary has only requires read access but not write access to the email
983 data being transmitted. There are two variations of this type of attack include:

- 984 • The adversary may have access to the packets that make up the email message as they move
985 over a network. This access may come in the form of a passive wiretapping or eavesdropping
986 attack.
- 987 • Software may be installed on a MTA that makes copies of email messages and delivers them
988 to the adversary. For example, the adversary may have modified the target’s email account so
989 that a copy of every received message is forwarded to an email address outside the
990 organization.

991 Encryption is the best defense against eavesdropping attacks. Encrypting the email messages
992 either between MTAs (using TLS as described in Section 5) can thwart attacks involving packet
993 interception. End-to-end encryption (described in Section 5.3) can protect against both
994 eavesdropping attacks as well as MTA software compromise.

995 A second form of passive attack is a traffic analysis attack. In this scenario, the adversary is not
996 able to directly interpret the contents of an email message, mostly due to the fact that the
997 message is encrypted. However, since inference of information is still possible in certain
998 circumstances (depending upon interaction or transaction context) from the observation of
999 external traffic characteristics (volume and frequency of traffic between any two entities) and
1000 hence the occurrence of this type of attack constitutes a confidentiality threat.

1001 Although the impact of traffic analysis is limited in scope, it is much easier to perform this attack
1002 in practice—especially if part of the email transmission media uses a wireless network, if packets
1003 are sent over a shared network, or if the adversary has the ability to run network management or
1004 monitoring tools against the victim’s network. TLS encryption provides some protection against
1005 traffic analysis attacks, as the attacker is prevented from seeing any message headers. End-to-end
1006 email encryption protocols do not protect message headers, as the headers are needed for
1007 delivery to the destination mailbox. Thus, organizations may wish to employ both kinds of
1008 encryption to secure email from confidentiality threats.

1009 **3.3 Availability-related Threats**

1010 An availability threat exists in the email infrastructure (or for that matter any IT infrastructure),
1011 when potential events occur that prevents the resources of the infrastructure from functioning
1012 according to their intended purpose. The following availability-related threats exist in an email
1013 infrastructure.

- 1014 • Email Bombing
- 1015 • Unsolicited Bulk Email (UBE) – also called “Spam”
- 1016 • Availability of email servers

1017 3.3.1 Email Bombing

1018 *Email bombing* is a type of attack that involves sending several thousands of identical messages
1019 to a particular mailbox in order to cause overflow. These can be many large messages or a very
1020 large number of small messages. Such a mailbox will either become unusable for the legitimate
1021 email account holder to access. No new messages can be delivered and the sender receives an
1022 error asking to resend the message. In some instances, the mail server may also crash.

1023 The motive for Email bombing is denial of service (DoS) attack. A DoS attack by definition
1024 either prevents authorized access to resources or causes delay (e.g., long response times) of time-
1025 critical operations. Hence email bombing is a major availability threat to an email system since it
1026 can potentially consume substantial Internet bandwidth as well as storage space in the message
1027 stores of recipients. An email bombing attack can be launched in several ways.

1028 There are many ways to perpetrate an email bombing attack, including:

- 1029
- 1030 • An adversary can employ any (anonymous) email account to constantly bombard the victim's
1031 email account with arbitrary messages (that may contain very long large attachments).
- 1032 • If an adversary controls an MTA, the adversary can run a program that automatically
1033 composes and transmits messages.
- 1034 • An adversary can post a controversial or significant official statement to a large audience
1035 (e.g., a social network) using the victim's return email address. Humans will read the
1036 message and respond with individually crafted messages that may be very hard to filter with
1037 automated techniques. The responses to this posting will eventually flood the victim's email
1038 account.
- 1039 • An adversary may subscribe the victim's email address to many mailing lists ("listservers").
1040 The generated messages are then sent to the victim, until the victim's email address is
1041 unsubscribed from those lists.

1042 Possible countermeasures for protection against Email bombing are: (a) Use filters that are based
1043 on the logic of filtering identical messages that are received within a chosen short span of time
1044 and (b) configuring email receivers to block messages beyond a certain size and/or attachments
1045 that exceed a certain size.

1046 3.3.2 Unsolicited Bulk Email (Spam)

1047 *Spam* is the internet slang for unsolicited bulk email (UBE). Spam refers to indiscriminately sent
1048 messages that are unsolicited, unwanted, irrelevant and/or inappropriate, such as commercial
1049 advertising in mass quantities. Thus spam, generally, is not targeted towards a particular email
1050 receiver or domain. However, when the volume of spam coming into a particular email domain
1051 exceeds a certain threshold, it has availability implications since it results in increased network
1052 traffic and storage space for message stores. Spam that looks for random gullible victims or
1053 targets particular users or groups of users with malicious intent (gathering sensitive information
1054 for physical harm or for committing financial fraud) is called phishing. From the above
1055 discussion of email bombing attacks, it should be clear that spam can sometimes be a type of
1056 email bombing.

1057 Protecting the email infrastructure against spam is a challenging problem. This is due to the fact
 1058 that the two types of techniques currently used to combat spam have limitations. See Section 6
 1059 for a more detailed discussion of unsolicited bulk email.

1060 3.3.3 Availability of Email Servers

1061 The email infrastructure just like any other IT infrastructure should provide for fault tolerance
 1062 and avoid single points of failure. A domain with only a single email server or a domain with
 1063 multiple email servers, but all located in a single IP subnet is likely to encounter availability
 1064 problems either due to software glitches in MTA, hardware maintenance issues or local data
 1065 center network problems. The typical measures for ensuring high availability of email as a
 1066 service are: (a) Multiple MTAs with placement based on the email traffic load encountered by
 1067 the enterprise; and, (b) Distribution of email servers in different network segments or even
 1068 physical locations.

1069 3.4 Summary of Threats and Mitigations

1070 A summary of the email related threats to an enterprise is given in Table 3-1. This includes
 1071 threats to both the email the receiver and the purported sender - often spoofed, and who may not
 1072 be aware an email was sent using their domain. Mitigations are listed in the final column to
 1073 reduce the risk of the attack being successful, or to prevent them.

1074

Table 3-1 Email-based Threats and Mitigations:

Threat	Impact on Purported Sender	Impact on Receiver	Mitigation
Email sent by unauthorized MTA in enterprise (e.g. malware botnet)	Loss of reputation, valid email from enterprise may be blocked as possible spam/phishing attack.	UBE and/or email containing malicious links may be delivered into user inboxes	Deployment of domain-based authentication techniques (see Section 4). Use of digital signatures over email (see Section 6). Blocking outbound port 25 for all non-mail sending hosts.
Email message sent using spoofed or unregistered sending domain	Loss of reputation, valid email from enterprise may be blocked as possible spam/phishing attack.	UBE and/or email containing malicious links may be delivered into user inboxes	Deployment of domain-based authentication techniques (see Section 4). Use of digital signatures over email (see Section 6).

Threat	Impact on Purported Sender	Impact on Receiver	Mitigation
Email message sent using forged sending address or email address (i.e. phishing, spear phishing)	Loss of reputation, valid email from enterprise may be blocked as possible spam/phishing attack.	UBE and/or email containing malicious links may be delivered. Users may inadvertently divulge sensitive information or PII.	Deployment of domain-based authentication techniques (see Section 4). Use of digital signatures over email (see Section 6). DNS Blacklists (see Section 7).
Email modified in transit	Leak of sensitive information or PII.	Leak of sensitive information, altered message may contain malicious information	Use of TLS to encrypt email transfer between servers (see Section 5). Use of end-to-end email encryption (see Section 7). Use of DMKIM to identify message mods (see Section 4.5).
Disclosure of sensitive information (e.g. PII) via monitoring and capturing of email traffic	Leak of sensitive information or PII.	Leak of sensitive information, altered message may contain malicious information	Use of TLS to encrypt email transfer between servers (see Section 5). Use of end-to-end email encryption (see Section 7).
Disclosure of metadata of email messages	Possible privacy violation	Possible privacy violation	Use of TLS to encrypt email transfer between servers (see Section 5).
Unsolicited Bulk Email (i.e. spam)	None, unless purported sender is spoofed.	UBE and/or email containing malicious links may be delivered into user inboxes	Techniques to address UBE (see Section 7).
DoS/DDoS attack against an enterprises' email servers	Inability to send email.	Inability to receive email.	Multiple mail servers, use of cloud-based email providers. DNS Blacklists (see Section 7).

Threat	Impact on Purported Sender	Impact on Receiver	Mitigation
Email containing links to malicious site or malware.	None, unless purported sending domain spoofed.	Potential malware installed on enterprise systems.	Techniques to address UBE (Section 7). “Detonation chambers” to open links/attachments for malware scanning before delivery.

1075

1076 **3.5 Security Recommendations Summary**

1077 **Security Recommendation 3-1:** To mitigate the risk of unauthorized sender, an enterprise
 1078 administrator should block outbound port 25 (except for authorized mail senders) and look to
 1079 deploy firewall or intrusion detection systems (IDS) that can alert the administrator when an
 1080 unauthorized host is sending mail via SMTP to the Internet.

1081 **Security Recommendation 3-2:** Systems that are not involved in the organization’s email
 1082 infrastructure should not be configured to run Mail Transfer Agents (MTAs). Internal systems
 1083 that need to send mail should be configured to use a trusted internal MSA.

1084 **Security Recommendation 3-3:** To mitigate the risk of unauthorized receivers, an enterprise
 1085 administrator should block inbound port 25 and look to deploy firewall or intrusion detection
 1086 systems (IDS) that can alert the administrator when an unauthorized host is accepting mail via
 1087 SMTP from the Internet.

1088 **4 Authenticating a Sending Domain and Individual Mail Messages**

1089 **4.1 Introduction**

1090 RFC 5322 defines the Internet Message Format (IMF) for delivery over the Simple Mail Transfer
1091 Protocol (SMTP) [RFC5321], but in its original state any sender can write any envelope-From:
1092 address in the header (see Section 2.3.3). This envelope-From: address can however be
1093 overridden by malicious senders or enterprise mail administrators, who may have organizational
1094 reasons to rewrite the header, and so both [RFC 5321] and [RFC 5322] defined From: addresses
1095 can be aligned to some arbitrary form not intrinsically associated with the originating IP address.
1096 In addition, any man in the middle attack can modify a header or data content. New protocols
1097 were developed to detect these envelope-From: and message-From: address spoofing or
1098 modifications.

1099 Sender Policy Framework (SPF) [RFC4408] uses the Domain Name System (DNS) to allow
1100 domain owners to create records that associate the envelope-From: address domain name with
1101 one or more IP address blocks used by authorized MSAs. It is a simple matter for a receiving
1102 MTA to check a SPF TXT record in the DNS to confirm the purported sender of a message to the
1103 listed approved sending MTA is indeed authorized to transmit email messages for the domain
1104 listed in the envelope-From: address. Mail messages that do not pass this check may be marked,
1105 quarantined or rejected. SPF is described in subsection 4.4 below.

1106 The DomainKeys Identified Mail (DKIM) [RFC6376] protocol allows a sending MTA to
1107 digitally sign selected headers and the body of the message with a RSA signature and include the
1108 signature in a DKIM header that is attached to the message prior to transmission. The DKIM
1109 signature header field includes a selector, which the receiver can use to retrieve the public key
1110 from a record in the DNS to validate the DKIM signature over the message. So, validating the
1111 signature assures the receiver that the message has not been modified in transit – other than
1112 additional headers added by MTAs en route which are ignored during the validation. Use of
1113 DKIM also ties the email message to the domain storing the public key, regardless of the From:
1114 address (which could be different). DKIM is detailed in subsection 4.5.

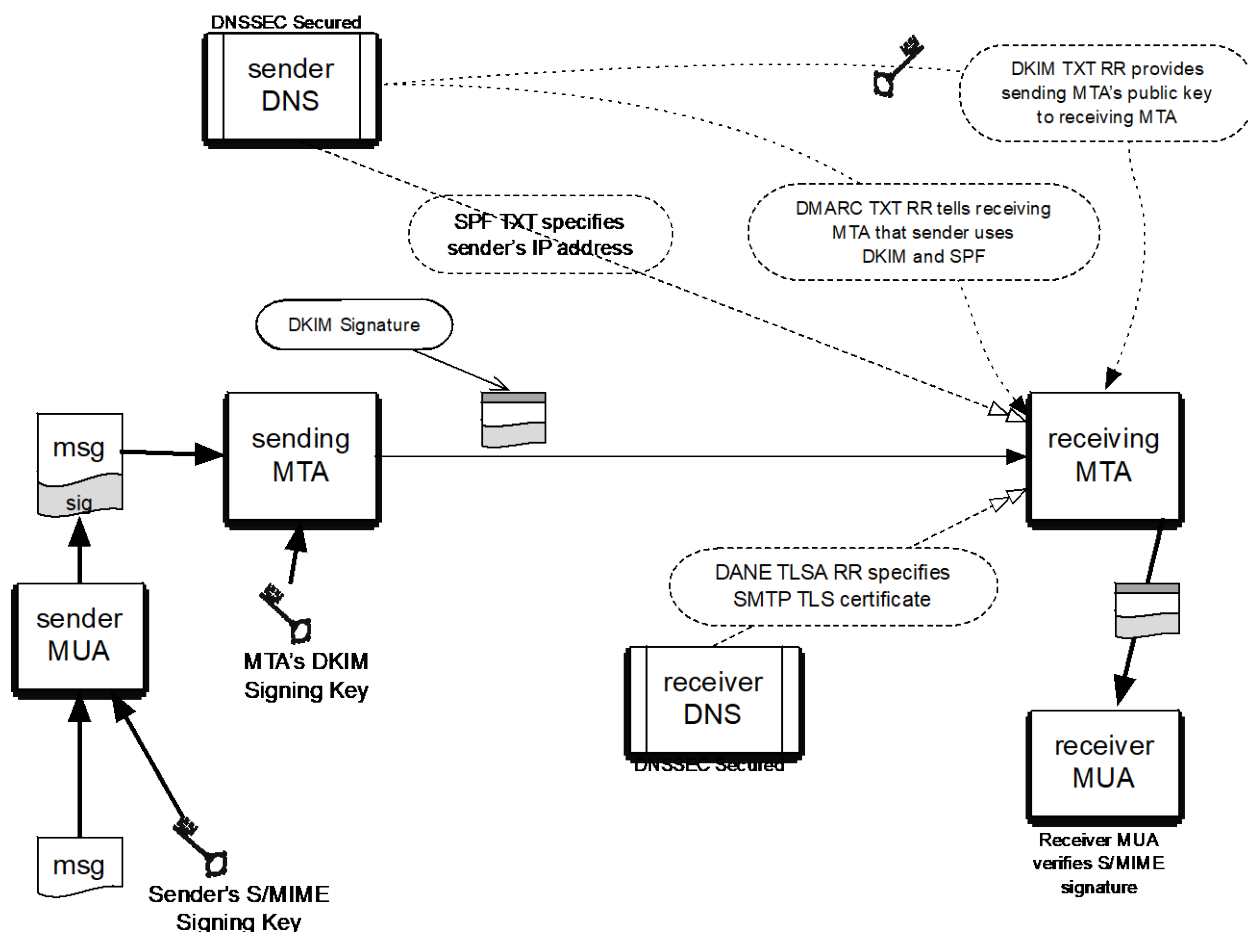

1115 Deploying SPF and DKIM may curb illicit activity against a sending domain, but the sender gets
1116 no indication of the extent of the beneficial (or otherwise) effects of these policies. Sending
1117 domain owners may choose to construct pairwise agreements with selected recipients to
1118 manually gather feedback, but this is not a scalable solution. The Domain-based Message
1119 Authentication, Reporting and Conformance protocol (DMARC) [RFC7489] institutes such a
1120 feedback mechanism, to let sending domain owners know the proportionate effectiveness of their
1121 SPF and DKIM policies, and to signal to receivers what action should be taken in various
1122 individual and bulk attack scenarios. After setting a policy to advise receivers to deliver,
1123 quarantine or reject messages that fail both SPF and DKIM, Email receivers then return DMARC
1124 aggregate and/or failure reports of email dispositions to the domain owner, who can review the
1125 results and potentially refine the policy. DMARC is described in subsection 4.6.

1126 While DMARC can do a lot to curb spoofing and phishing (Section 3.1.6 above), it does need
1127 careful configuration. Intermediaries that forward mail have many legitimate reasons to rewrite
1128 headers, usually related to legitimate activities such as operating mailing lists, mail groups, and

1129 end-user mail forwarding. It should be noted that mail server forwarding changes the source IP
 1130 address, and without rewriting the envelope-From: field, this can make SPF checks fail. On the
 1131 other hand, header rewriting, or adding a footer to mail content, may cause the DKIM signature
 1132 to fail. Both of these interventions can cause problems for DKIM validation and for message
 1133 delivery. Subsection 4.6 expands on the problems of mail forwarding, and its mitigations.

1134 SPF, DKIM and DMARC authenticate that the sending MTA is an authorized, legitimate sender
 1135 of email messages for the domain-part of the envelope-From: (and message-From: for DMARC)
 1136 address, but these technologies do not verify that the email message is from a specific individual
 1137 or logical account. That kind of assurance is provided by end-to-end security mechanisms such as
 1138 S/MIME (or OpenPGP). The DKIM and S/MIME/OpenPGP signature standards are not-
 1139 interfering: DKIM signatures go in the email header, while S/MIME/OpenPGP signatures are
 1140 carried as MIME body parts. The signatures are also complementary: a message is typically
 1141 signed by S/MIME or OpenPGP immediately after it is composed, typically by the sender's
 1142 MUA, and the DKIM signature is added after the message passes through the sender's MSA or
 1143 MTA.

1144 The interrelation of SPF, DKIM, DMARC, and S/MIME signatures are shown in the Figure 4-1
 1145 below:

1146 **Figure 4-1: the interrelationship of DNSSEC, SPF, DKIM, DMARC and S/MIME for assuring message**
 1147 **authenticity and integrity.**
 1148

1149 **4.2 Visibility to End Users**

1150 As mentioned above, the domain-based authentication protocols discussed in this section were
1151 designed with MTAs in mind. There was thought to be no need for information passed to the end
1152 recipient of the email. The results of SPF and DKIM checks are not normally visible in MUA
1153 components unless the end user views the message headers directly (and knows how to interpret
1154 them). This information may be useful to some end users who wish to filter messages based on
1155 these authentication results. [RFC7601] specifics how an MTA/MDA can add a new header to a
1156 message upon receipt that provides status information about any authentication checks done by
1157 the receiving MTA. Some MUAs make use of this information to provide visual cues (an icon,
1158 text color, etc.) to end users that this message passed the MTAs checks and was deemed valid.
1159 This does not explicitly mean that the email contents are authentic or valid, just that the email
1160 passed the various domain-based checks performed by the receiving MTA.

1161 Email administrators should be aware if the MUAs used in their enterprise can interpret and
1162 show results of the authentication headers to end users. Email administrators should educate end
1163 users about what the results mean when evaluating potential phishing/spam email as well as not
1164 assuming positive results means they have a completely secure channel.

1165 **4.3 Requirements for Using Domain-based Authentication Techniques for Federal** 1166 **Systems**

1167 As of the time of writing of this guidance document, the DHS Federal Network Resilience
1168 division (FNR) has called out the use of domain-based authentication techniques for email as
1169 part of the FY16 FISMA metrics [FISMAMET] for anti-phishing defenses. This includes the
1170 techniques discussed below. This section gives best-common-practice guidance of the domain-
1171 based authentication techniques listed (but not described) in [FISMAMET]. This document does
1172 not extend those requirements in anyway, but gives guidance on how to meet existing
1173 requirements.

1174 **4.4 Sender Policy Framework (SPF)**

1175 Sender Policy Framework (SPF) is a standardized way for the domain of the envelope-From:
1176 address to identify and assert the mail originators (i.e. mail senders) for a given domain. The
1177 sending domain does this by placing a specially formatted Text Resource Record (TXT RR) in
1178 the DNS database for the domain. The idea is that a receiving MTA can check the IP address of
1179 the connecting MTA against the purported sending domain (the domain-part of the envelope-
1180 From: address) and see if the domain vouches for the sending MTA. The receiving MTA does
1181 this by sending a DNS query to the purported sending domain for the list of valid senders.

1182 SPF was designed to address phishing and spam being sent by unauthorized senders (i.e.
1183 botnets). SPF does not stop all spam, in that spam email being sent from a domain that asserts its
1184 sending MTAs via an SPF record will pass all SPF checks. That is, a spammer can send email
1185 using an envelope-From: address using a domain that the spammer controls, and that email will
1186 not result in a failed SPF check. SPF checks fail when mail is received from a sending MTA
1187 other than those listed as approved senders for the envelope-From: domain. For example, an
1188 infected botnet of hosts in an enterprise may be sending spam on its own (i.e. not through the
1189 enterprises outgoing SMTP server), but those spam messages would be detected as the infected

1190 hosts would not be listed as valid senders for the enterprise domain, and would fail SPF checks.
1191 See [HERZBERG2009] for a detailed review of SPF and its effectiveness.

1192 4.4.1 Background

1193 SPF works by comparing the sender's IP address (IPv4 or IPv6, depending on the transport used
1194 to deliver the message) with the policy encoded in any SPF record found at the sending domain.
1195 That is, the domain-part of the envelope-From: address. This means that SPF checks can actually
1196 be applied before the bulk of the message is received from the sender. For example, in Fig 4-1,
1197 the sender with IP address 192.168.0.1 uses the envelope **MAIL FROM:** tag as
1198 **alice@example.org** even though the message header is **alice.sender@example.net**. The receiver
1199 queries for the SPF RR for example.org and checks if the IP address is listed as a valid sender. If
1200 it is listed, or no valid SPF record is found, the message is processed as usual. If not, the receiver
1201 may mark the message as a potential spoofed email, quarantine it for further (possibly
1202 administrator) analysis or reject the message, depending on the SPF policy and/or the policy
1203 discovered in any associated DMARC record (see subsection 4.5, below) for example.org.

```

1204 Client connects to port 25
1205 Server: 220 mx.example.com
1206 Client: HELO mta.example.net
1207 S: 250 Hello mta.example.net, I am glad to meet you

1214 Date: Today
1215 Subject: Meeting today
1216 ...

```

1217 **Fig 4-1: SMTP envelope header vs. message header**

1218 Because of the nature of DNS (which SPF uses for publication) an SPF policy is tied to one
1219 domain. That is, **@example.org** and **@sub.example.org** are considered separate domains just like
1220 **@example.net** and all three need their own SPF records. This complicates things for
1221 organizations that have several domains and subdomains that may (or may not) send mail. There
1222 is a way to publish a centralized SPF policy for a collection of domains using the **include:** tag
1223 (see Sec 4.2.2.2 below)

1224 SPF was first specified in [RFC4408] as an experimental protocol, since at the same time other,
1225 similar proposals were also being considered. Over time however, SPF became widely deployed
1226 and was finalized in [RFC7208] (and its updates). The changes between the final version and the
1227 original version are mostly minor, and those that base their deployments on the experimental
1228 version are still understood by clients that implement the final version. The most significant
1229 difference is that the final specification no longer calls for the use of a specialized RRTYPE

1230 (simply called a SPF RR) and instead calls for the sender policy to be encoded in a TXT
1231 Resource Record, in part because it proved too difficult to universally upgrade legacy DNS
1232 systems to accept a new RRType. Older clients may still look for the SPF RR, but the majority
1233 will fall back and ask for a TXT RR if it fails to find the special SPF RR. *Resolution of the*
1234 *Sender Policy Framework (SPF) and Sender ID Experiments* [RFC6686] presents the evidence
1235 that was used to justify the abandonment of the SPF RR.

1236 SPF was first called out as a recommended technology for federal agency deployment in 2011
1237 [SPF1]. It is seen as a way to reduce the risk of phishing email being delivered and used as to
1238 install malware inside an agency's network. Since it is relatively easy to check using the DNS,
1239 SPF is seen as a useful layer of email checks.

1240 **4.4.2 SPF on the Sender Side**

1241 Deploying SPF for a sending domain is fairly straightforward. It does not even require SPF
1242 aware code in mail servers, as receivers, not senders, perform the SPF processing. The only
1243 necessary actions are identifying IP addresses or ranges of permitted sending hosts for a given
1244 domain, and adding that information in the DNS as a new resource record.

1245 **4.4.2.1 Identifying Permitted Senders for a Domain and Setting the Policy**

1246 The first step in deploying SPF for a sending domain is to identify all the hosts that send email
1247 out of the domain (i.e. SMTP servers that are tasked with being email gateways to the Internet).
1248 This can be hard to do because:

- 1249 • There may be mail-sending SMTP servers within sub-units of the organization that are
1250 not known to higher-level management.
- 1251 • There may be other organizations that send mail on behalf of the organization (such as e-
1252 mail marketing firms or legitimate bulk-mailers).
- 1253 • Individuals who work remotely for the organization may send mail using their
1254 organization's email address but a local mail relay.

1255 If the senders cannot be listed with certainty, the SPF policy can indicate that receivers should
1256 not necessarily reject messages that fail SPF checks by using the “~” or “?” mechanisms, rather
1257 than the “-“ mechanism (see 4.3.2.2 below) in the SPF TXT record.

1258 Note: Deployment of DMARC [RFC7489] (discussed below) allows for reporting SPF check
1259 results back to sending domain owners, which allows senders to modify and improve their policy
1260 to minimize improper rejections.

1261 **4.4.2.2 Forming the SPF Resource Record**

1262 Once all the outgoing senders are identified, the appropriate policy can be encoded and put into
1263 the domain database. The SPF syntax is fairly rich and can express complex relationships
1264 between senders. Not only can entities be identified and called out, but the SPF statement can
1265 also request what emphasis should be placed on each test.

1266 SPF statements are encoded in ASCII text (as they are stored in DNS TXT resource records) and

1267 checks are processed in left to right order. Every statement begins with **v=spf1** to indicate that
 1268 this is an SPF (version 1) statement⁷.

1269 Other mechanisms are listed in Table 4-1:

1270

Table 4-1: SPF Mechanisms

Tag	Description
ip4:	Specifies an IPv4 address or range of addresses that are authorized senders for a domain.
ip6:	Specifies an IPv6 address or range of addresses that are authorized senders for a domain.
a	Asserts that the IP address listed in the domain's primary A RR is authored to send mail.
mx	Asserts that the listed hosts for the MX RR's are also valid senders for the domain.
include:	Lists another domain where the receiver should look for an SPF RR for further senders. This can be useful for large organizations with many domains or sub-domains that have a single set of shared senders. The include: mechanism is recursive, in that the SPF check in the record found is tested in its entirety before proceeding. It is not simply a concatenation of the checks.
all	Matches every IP address that has not otherwise been matched.

1271

1272 Each mechanism in the string is separated by whitespace. In addition, there are qualifiers that can
 1273 be used for each mechanism (Table 4-2):

1274

⁷ Note that there is a technology called SenderID that uses "v=spf2.0", but it is not an updated version of SPF, but a different protocol, not recommended in these guidelines.

1275

1276

Table 4-2: SPF Mechanism Qualifiers

Qualifier	Description
+	The given mechanism check must pass. This is the default mechanism and does not need to be explicitly listed.
-	The given mechanism is not allowed to send email on behalf of the domain.
~	The given mechanism is in transition and if an email is seen from the listed host/IP address, that it should be accepted but marked for closer inspection.
?	The SPF RR explicitly states nothing about the mechanism. In this case, the default behavior is to accept the email. (This makes it equivalent to “+” unless some sort of discrete or aggregate message review is conducted).

1277 There are other mechanisms available as well that are not listed here. Administrators interested in
 1278 seeing the full depth of the SPF syntax are encouraged to read the full specification in
 1279 [RFC7208]. To aid administrators, there are some online tools⁸ that can be used assist in the
 1280 generation and testing of an SPF record. These tools take administrator input and generate the
 1281 text that the administrator then places in a TXT RR in the given domain's zone file.

1282 4.4.2.3 Example SPF RRs

1283 Some examples of the mechanisms for SPF are given below. In each example, the purported
 1284 sender in the SMTP envelope is **example.com**

1285 The given domain has one mail server that both sends and receives mail. No other system is
 1286 authorized to send mail. The resulting SPF RR would be:

1287 **example.com IN TXT "v=spf1 mx -all"**

1288 The given enterprise has a DMZ that allows hosts to send mail, but is not sure if other senders
 1289 exist. As a temporary measure, they list the SPF as:

1290 **example.com IN TXT "v=spf1 ip4:192.168.1.0/16 ~all"**

1291 The enterprise has several domains for projects, but only one set of sending MTAs. So for each
 1292 domain, there is an SPF RR with the **include:** declaration pointing to a central TXT RR with the
 1293 SPF policy that covers all the domains. For example, each domain could have:

1294 **example.com IN TXT "v=spf1 include:spf.example.net."**

1295 The follow up query for the spf.example.net then has:

⁸ For example: <http://www.mailradar.com/spf/>

1296 **spf.example.net** **IN TXT "v=spf1 ip4:192.168.0.1 ..."**

1297 This makes SPF easier to manage for an enterprise with several domains and/or public
1298 subdomains. Administrators only need to edit **spf.example.net** to make changes to the SPF RR
1299 while the other SPF RR's in the other domains simply use the **include:** tag to reference it. No
1300 email should originate from the domain:

1301 **example.com** **IN TXT "v=spf1 -all"**

1302 The above should be added to all domains that do not send mail to prevent them being used by
1303 phishers looking for sending domains to spoof that they believe may not be monitored as closely
1304 as those that accept and send enterprise email. This is an important principle for domains that
1305 think they are immune from email related threats. Domain names that are only used to host web
1306 or services are advised to publish a “-all” record, to protect their reputation.

1307 Notice that semicolons are not permitted in the SPF TXT record.

1308 **Security Recommendation 4-1:** Organizations are recommended to deploy SPF to specify
1309 which IP addresses are authorized to transmit email on behalf of the domain. Domains controlled
1310 by an organization that are not used to send email, for example Web only domains, should
1311 include an SPF RR with the policy indicating that there are no valid email senders for the given
1312 domain.

1313 **4.4.3 SPF and DNS**

1314 Since SPF policies are now only encoded in DNS TXT resource records, no specialized software
1315 is needed to host SPF RRs. Organizations can opt to include the old (no longer mandated) unique
1316 SPF RRType as well, but it is usually not needed, as clients that still query for the type
1317 automatically query for a TXT RR if the SPF RR is not found.

1318 Organizations that deploy SPF should also deploy DNS security (DNSSEC) [RFC4033],
1319 [RFC4034], [RFC4035]. DNSSEC provides source authentication and integrity protection for
1320 DNS data. SPF RRs in DNSSEC signed zones cannot be altered or stripped from responses
1321 without DNSSEC aware receivers detecting the attack. Its use is more fully described in Section
1322 5.

1323 **4.4.3.1 Changing an Existing SPF Policy**

1324 Changing the policy statement in an SPF RR is straightforward, but requires timing
1325 considerations due to the caching nature of DNS. It may take some time for the new SPF RR to
1326 propagate to all authoritative servers. Likewise, the old, outgoing SPF RR may be cached in
1327 client DNS servers for the length of the SPF's TXT RR Time-to-Live (TTL). An enterprise
1328 should be aware that some clients might still have the old version of the SPF policy for some
1329 time before learning the new version. To minimize the effect of DNS caching, it is useful to
1330 decrease the DNS timeout to a small period of time (e.g. 300 seconds) before making changes,
1331 and then restoring DNS to a longer time period (e.g. 3600 seconds) after the changes have been
1332 made, tested, and confirmed to be correct.

1333 4.4.4 Considerations for SPF when Using Cloud Services or Contracted Services

1334 When an organization outsources its email service (whole or part) to a third party such as a cloud
 1335 provider or contracted email service, that organization needs to make sure any email sent by
 1336 those third parties will pass SPF checks. To do this, the enterprise administrator should include
 1337 the IP addresses of third party senders in the enterprise SPF policy statement RR. Failure to
 1338 include all the possible senders could result in valid email being rejected due to a failure when
 1339 doing the SPF check.

1340 Including third-parties to an SPF RR is done by adding the IP addresses/hostnames individually,
 1341 or using the **include:** tag to reference a third party's own SPF record (if one exists). In general, it
 1342 is preferable to use the **include:** mechanism, as the mechanism avoids hard-coding IP addresses
 1343 in multiple locations. The **include:** tag does have a hard limit on the number of “chained” **include:**
 1344 tag that a client will look up to prevent an endless series of queries. This value is ten unique DNS
 1345 lookups by default.

1346 For instance, if **example.com** has its own sending MTA at 192.0.0.1 but also uses a third party
 1347 (**third-example.net**) to send non-transactional email as well, the SPF RR for example.com would
 1348 look like:

```
1349 example.com IN TXT "v=spf1 ip4:192.0.0.1  

  1350 include:third-example.net -all"  

  1351
```

1352 As mentioned above, the **include:** mechanism does not simply concatenate the policy tests of the
 1353 included domain (here: **third-example.net**), but performs all the checks in the SPF policy
 1354 referenced and returns the final result. An administrator should not include the modifier "+"
 1355 (requiring the mechanism to pass in order for the whole check to pass) to the **include:** unless they
 1356 are also in control of the included domain, as any change to the SPF policy in the included
 1357 domain will affect the SPF validation check for the sending domain.

1358 4.4.5 SPF on the Receiver Side

1359 Unlike senders, receivers need to have SPF-aware mail servers to check SPF policies. SPF has
 1360 been around in some form (either experimental or finalized) and available in just about all major
 1361 mail server implementations. There are also patches and libraries available for other
 1362 implementations to make them SPF-aware and perform SPF queries and processing⁹. There is
 1363 even a plug-in available for the open-source Thunderbird Mail User Agent so end users can
 1364 perform SPF checks even if their incoming mail server does not.¹⁰

1365 As mentioned above, SPF uses the envelope-From: address domain-part and the IP address of the
 1366 sender. This means that SPF checks can be started before the actual text of the email message is
 1367 received. Alternatively, messages can be quickly received and held in quarantine until all the

⁹ A list of some SPF implementations can be found at <http://www.openspf.org/Implementations>

¹⁰ See <https://addons.mozilla.org/en-us/thunderbird/addon/sender-verification-anti-phish/>

1368 checks are finished. In either event, checks must be completed before the mail message is sent to
1369 an end user's inbox (unless the only SPF checks are performed by the end user using their own
1370 MUA).

1371 The resulting action based on the SPF checks depends on local receiver policy and the statements
1372 in the purported sending domain's SPF statement. The action should be based on the modifiers
1373 (listed above) on each mechanism. If no SPF TXT RR is returned in the query, or the SPF has
1374 formatting errors that prevent parsing, the default behavior is to accept the message. This is the
1375 same behavior for mail servers that are not SPF-aware.

1376 **4.4.5.1 SPF Queries and DNS**

1377 Just as an organization that deploys SPF should also deploy DNSSEC [SP800-81], receivers that
1378 perform SPF processing should also perform DNSSEC validation (if possible) on responses to
1379 SPF queries. A mail server should be able to send queries to a validating DNS recursive server if
1380 it cannot perform its own DNSSEC validation.

1381 **Security Recommendation 4-2:** Organizations should deploy DNSSEC for all DNS name
1382 servers and validate DNSSEC queries on all systems that receive email.

1383 **4.5 DomainKeys Identified Mail (DKIM)**

1384 DomainKeys Identified Mail (DKIM) permits a person, role, or organization that owns the
1385 signing domain to claim some responsibility for a message by associating the domain with the
1386 message. This can be an author's organization, an operational relay, or one of their agents. DKIM
1387 separates the question of the identity of the signer of the message from the purported author of
1388 the message. Assertion of responsibility is validated through a cryptographic signature and by
1389 querying the signer's domain directly to retrieve the appropriate public key. Message transit from
1390 author to recipient is through relays that typically make no substantive change to the message
1391 content and thus preserve the DKIM signature. Because the DKIM signature covers the message
1392 body, it also protects the integrity of the email communication. Changes to a message body will
1393 result in a DKIM signature validation failure, which is why some mailing lists (that add footers
1394 to email messages) will cause DKIM signature validation failures (discussed below).

1395 A DKIM signature is generated by the original sending MTA using the email message body and
1396 headers and places it in the header of the message along with information for the client to use in
1397 validation of the signature (i.e. key selector, algorithm, etc.). When the receiving MTA gets the
1398 message, it attempts to validate the signature by looking for the public key indicated in the
1399 DKIM signature. The MTA issues a DNS query for a text resource record (TXT RR) that
1400 contains the encoded key.

1401 Like SPF (see Section 4.4), DKIM allows an enterprise to vouch for an email message sent from
1402 a domain it does not control (as would be listed in the SMTP envelope). The sender only needs
1403 the private portion of the key to generate signatures. This allows an enterprise to have email sent
1404 on its behalf by an approved third party. The presence of the public key in the enterprises' DNS
1405 implies that there is a relationship between the enterprise and the sender.

1406 Since DKIM requires the use of asymmetric cryptographic key pairs, enterprises must have a key

1407 management plan in place to generate, store and retire key pairs. Administrative boundaries
1408 complicate this plan if one organization sends mail on another organization's behalf.

1409 **4.5.1 Background**

1410 DKIM was originally developed as part of a private sector consortium and only later transitioned
1411 to an IETF standard. The threat model that the DKIM protocol is designed to protect against was
1412 published as [RFC4686], and assumes bad actors with an extensive corpus of mail messages
1413 from the domains being impersonated, knowledge of the businesses being impersonated, access
1414 to business public keys, and the ability to submit messages to MTAs and MSAs at many
1415 locations across the Internet. The original DKIM protocol specification was developed as
1416 [RFC4871], which is now considered obsolete. The specification underwent several revisions and
1417 updates and the current version of the DKIM specification is published as [RFC6376].

1418 **4.5.2 DKIM on the Sender Side**

1419 Unlike SPF, DKIM requires specialized functionality on the sender MTA to generate the
1420 signatures. Therefore, the first step in deploying DKIM is to ensure that the organization has an
1421 MTA that can support the generation of DKIM signatures. DKIM support is currently available
1422 in some implementations or can be added using open source filters¹¹. Administrators should
1423 remember that since DKIM involves digital signatures, sending MTAs should also have
1424 appropriate cryptographic tools to create and store keys and perform cryptographic operations.

1425 **4.5.3 Generation and Distribution of the DKIM Key Pair**

1426 The next step in deploying DKIM, after ensuring that the sending MTA is DKIM-aware, is to
1427 generate a signing key pair.

1428 Cryptographic keys should be generated in accordance with NIST SP 800-57,
1429 “Recommendations for Key Management” [SP800-57pt1] and NIST SP 800-133,
1430 “Recommendations for Cryptographic Key Generation.” [SP800-133] Although there exist web-
1431 based systems for generating DKIM public/private key pairs and automatically producing the
1432 corresponding DNS entries, such systems should not be used for federal information systems
1433 because they may compromise the organization’s private key.

1434 Currently the DKIM standard specifies that messages must be signed with one of two digital
1435 signature algorithms: RSA/SHA-1 and RSA/SHA-256. Of these, only RSA/SHA-256 is
1436 approved for use by government agencies with DKIM, as the hash algorithm SHA-1 is no longer
1437 approved for use in conjunction with digital signatures (see Table 4-1).

1438

¹¹ Mail filters are sometimes called “milters.” A milter is a process subordinate to a MTA that can be deployed to perform special message header or body processing. More information about milters can be found at http://www.sendmail.com/sm/partners/milter_partners/open_source_milter_partners/

1439

1440

Table 4-3: Recommended Cryptographic Key Parameters

DKIM Specified Algorithm	Approved for Government Use?	Recommended Length	Recommended Lifetime
RSA/SHA-1	NO	n/a	n/a
RSA/SHA-256	YES	2048 bits	1-2 years

1441

1442 Once the key pair is generated, the administrator should determine a selector value to use with
 1443 the key. A DKIM selector value is a unique identifier for the key that is used to distinguish one
 1444 DKIM key from any other potential keys used by the same sending domain, allowing different
 1445 MTAs to be configured with different signing keys. This selector value is needed by receiving
 1446 MTAs to query the validating key.

1447 The public part of the key pair is stored in a the DKIM TXT Resource Record (RR). This record
 1448 should be added to the organization's DNS server and tested to make sure that it is accessible
 1449 both within and outside the organization.

1450 The private part of the key pair is used by the MTA to sign outgoing mail. Administrators must
 1451 configure their mail systems to protect the private part of the key pair from exposure to prevent
 1452 an attacker from learning the key and using it to spoof email with the victim domain's DKIM
 1453 key. For example, if the private part of the key pair is kept in a file, file permissions must be set
 1454 so that only the user under which the MTA is running can read it.

1455 As with any cryptographic keying material, enterprises should use a Cryptographic Key
 1456 Management System (CKMS) to manage the generation, distribution, and lifecycle of DKIM
 1457 keys. Federal agencies are encouraged to consult NIST SP 800-130 [SP800-130] and NIST SP
 1458 800-152 [SP800-152] for guidance on how to design and implement a CKMS within an agency.

1459 **Security Recommendation 4-3:** Federal agency administrators shall only use keys with
 1460 approved algorithms and lengths for use with DKIM.

1461 **Security Recommendation 4-4:** Administrators should insure that the private portion of the
 1462 key pair is adequately protected on the sending MTA and that only the MTA software has read
 1463 privileges for the key. Federal agency administrators should follow FISMA control SC-12
 1464 [SP800-53] guidance with regards to distributing and protecting DKIM key pairs.

1465 **Security Recommendation 4-5:** Each sending MTA should be configured with its own
 1466 private key and its own selector value, to minimize the damage that may occur if a private key is
 1467 compromised. This private key must have protection against both accidental disclosure or
 1468 attacker's attempt to obtain or modify.

1469 **4.5.4 Example of a DKIM Signature**

1470 Below is an example of a DKIM signature as would be seen in an email header. A signature is
 1471 made up of a collection of **tag=value** pairs that contain parameters needed to successfully validate
 1472 the signature as well as the signature itself. An administrator usually cannot configure the tags
 1473 individually as these are done by the MTA functionality that does DKIM, though some require
 1474 configuration (such as the selector, discussed above). Some common tags are described in Table
 1475 4-4.

1476

Table 4-4: DKIM Signature Tag and Value Descriptions

Tag	Name	Description
v=	Version	Version of DKIM in use by the signer. Currently the only defined value is "1".
a=	Algorithm	The algorithm used (rsa-sha1 or rsa-sha256)
b=	Signature ("base")	The actual signature, encoded as a base64 string in textual representations
bh=	Signature Hash ("base hash")	The hash of the body of the email message encoded as a base64 string.
d=	DNS	The DNS name of the party vouching for the signature. This is used to identify the DNS domain where the public key resides.
i=	Identifier	The identifier is normally either the same as, or a subdomain of, the d= domain.
s=	Selector	Required selector value. This, together with the domain identified in the d= tag, is used to form the DNS query used to obtain the key that can validate the DKIM signature.
t=	Timestamp	The time the DKIM signature was generated.
x=	Signature expiration	An optional value to state a time after which the DKIM signature should no longer be considered valid. Often included to provide anti-replay protection.
l=	Length	Length specification for the body in octets. So the signature can be computed over a given length, and this will not affect authentication in the case that a mail forwarder adds an additional suffix to the message.

1477

1478 Thus, a DKIM signature from a service provider sending mail on behalf of **example.gov** might
 1479 appear as an email header:

1480 **DKIM-Signature: v=1; a=rsa-sha256; d=example.gov; c=simple; i=@gov-**
 1481 **sender.example.gov; t=1425066098; s=adkimkey; bh=base64 string; b=base64 string**

1482 Note that, unlike SPF, DKIM requires the use of semicolons between statements.

1483 **4.5.5 Generation and Provisioning of the DKIM Resource Record**

1484 The public portion of the DKIM key is encoded into a DNS TXT Resource Record (RR) and
 1485 published in the zone indicated in the FROM: field of the email header. The DNS name for the
 1486 RR uses the selector the administrator chose for the key pair and a special tag to indicate it is for
 1487 DKIM ("**_domainkey**"). For example, if the selector value for the DKIM key used with
 1488 example.gov is "dkimkey", then the resulting DNS RR has the name
 1489 **dkimkey._domainkey.example.gov**.

1490 Like SPF, there are other **tag=value** pairs that need to be included in a DKIM RR. The full list of
 1491 tags is listed in the specification [RFC6376], but relevant ones are listed below:

1492

Table 4-5: DKIM RR Tag and Value Descriptions

Tag	Name	Description
v=	Version	Version of DKIM in use with the domain and required for every DKIM RR. The default value is " DKIM1 ".
k=	Key type	The default is rsa and is optional, as RSA is currently the only specified algorithm used with DKIM
p=	Public Key	The encoded public key (base64 encoded in text zone files). An empty value indicates that the key with the given selector field has been revoked.
t=	Optional flags	One defined flag is " y " indicating that the given domain is experimenting with DKIM and signals to clients to treat signed messages as unsigned (to prevent messages that failed validation from being dropped). The other is " s " to signal that there must be a direct match between the " d= " tag and the " i= " tag in the DKIM signature. That is, the " i= " tag must not be a subdomain of the " d= " tag.

1493 **4.5.6 Example of a DKIM RR**

1494 Below is an example for the DKIM key that would be used to validate the DKIM signature
 1495 above. Here, not all the flags are given:

1496 **adkimkey._domainkey.example.gov. IN TXT "v=DKIM1; k=rsa;**
1497 **p=<base64 string>"**
1498

1499 **4.5.7 DKIM and DNS**

1500 Since DKIM public keys are encoded in DNS TXT resource records, no specialized software is
1501 needed to host DKIM public keys. Organizations that deploy DKIM should also deploy DNS
1502 security (DNSSEC) [RFC4033] [RFC4034] [RFC4035]. DNSSEC provides source
1503 authentication and integrity protection for DNS data. This prevents attackers from spoofing, or
1504 intercepting and deleting responses for receivers' DKIM key TXT queries.

1505 **Security Recommendation 4-6:** Organizations should deploy DNSSEC to provide
1506 authentication and integrity protection to the DKIM DNS resource records.

1507 **4.5.8 DKIM Operational Considerations**

1508 There are several operations an email administrator will need to perform to maintain DKIM for
1509 an email service. New email services are acquired; DKIM keys are introduced, rolled (i.e.
1510 changed), and eventually retired, etc. Since DKIM requires the use of DNS, administrators need
1511 to take the nature of DNS into account when performing maintenance operations. [RFC5863]
1512 describes the complete set of maintenance operations for DKIM in detail, but the three most
1513 common operations are summarized below.

1514 **4.5.8.1 Introduction of a New DKIM Key**

1515 When initially deploying DKIM for enterprise email, or a new email service to support an
1516 organization, an administrator should insure that the corresponding public key is available for
1517 validation. Thus, the DNS entry with the DKIM public portion should be published in the
1518 sender's domain before the sending MTA begins using the private portion to generate signatures.
1519 The order should be:

- 1520 **1.** Generate a DKIM key pair and determine the selector that will be used by the MTA(s).
 - 1521 **2.** Generate and publish the DKIM TXT RR in the sending domain's DNS.
 - 1522 **3.** Ensure that the DKIM TXT RR is returned in queries.
 - 1523 **4.** Configure the sending MTA(s) to use the private portion.
 - 1524 **5.** Begin using the DKIM key pair with email.
- 1525

1526 **4.5.8.2 Changing an Active DKIM Key Pair**

1527 DKIM keys may change for various purposes: suspected weakness or compromise, scheduled
1528 policy, change in operator, or because the DKIM key has reached the end of its lifetime.

1529 Changing, or rolling, a DKIM key pair consists of introducing a new DKIM key before its use
1530 and keeping the old, outgoing key in the DNS long enough for clients to obtain it to validate
1531 signatures. This requires multiple DNS changes with a wait time between them. The relevant
1532 steps are:

- 1533 1. Generate a new DKIM key pair.
- 1534 2. Generate a new DKIM TXT RR, with a different selector value than the outgoing DKIM
- 1535 key and publish it in the enterprise's DNS. *At this point, the DNS will be serving both the*
- 1536 *old and the new DKIM entries*
- 1537 3. Reconfigure the sending MTA(s) to use the new DKIM key.
- 1538 4. Validate the correctness of the public key.
- 1539 5. Begin using the new DKIM key for signature generation.
- 1540 6. Wait a period of time
- 1541 7. Delete the outgoing DKIM TXT RR.
- 1542 8. Delete or archive the retired DKIM key according to enterprise policy.
- 1543

1544 The necessary period of time to wait before deleting the outgoing DKIM key's TXT RR cannot
 1545 be a universal constant value due to the nature of DNS and SMTP (i.e. mail queuing). An
 1546 enterprise cannot be certain when all of its email has passed DKIM checks using its old key. An
 1547 old DKIM key could still be queried for by a receiving MTA hours (or potentially days) after the
 1548 email had been sent. Therefore, the outgoing DKIM key should be kept in the DNS for a period
 1549 of time (potentially a week) before final deletion.

1550 If it is necessary to revoke or delete a DKIM key, it can be immediately retired by either be
 1551 removing the key's corresponding DKIM TXT RR or by altering the RR to have a blank `p=`.
 1552 Either achieves the same effect (the client can no longer validate the signature), but keeping the
 1553 DKIM RR with a blank `p=` value explicitly signals that the key has been removed.

1554 Revoking a key is similar to deleting it but the enterprise may pre-emptively delete (or change)
 1555 the DKIM RR before the sender has stopped using it. This scenario is possible when an
 1556 enterprise wishes to break DKIM authentication and does not control the sender (i.e. a third party
 1557 or rogue sender). In these scenarios, the enterprise can delete or change the DKIM RR in order to
 1558 break validation of DKIM signatures. Additional deployment of DMARC (see Section 4.5) can
 1559 be used to indicate that this DKIM validation failure should result in the email being rejected or
 1560 deleted.

1561 **4.5.9 DKIM on the Receiver Side**

1562 On the receiver side, email administrators should first make sure their MTA implementation have
 1563 the functionality to verify DKIM signatures. Most major implementations have the functionality
 1564 built-in, or can be included using open source patches or a mail filter (often called a *militer*). In
 1565 some cases, the administrator may need to install additional cryptographic libraries to perform
 1566 the actual validation.

1567 **4.5.9.1 DKIM Queries in the DNS**

1568 Just as an organization that deploys DKIM should deploy DNSSEC, receivers that perform
 1569 DKIM processing should also perform DNSSEC validation (if possible) on responses to DKIM
 1570 TXT queries. A mail server should be able to send queries to a validating DNS recursive server if
 1571 it cannot perform its own DNSSEC validation.

1572 **Security Recommendation 4-7:** Organizations should enable DNSSEC validation on DNS

1573 servers used by MTAs that verify DKIM signatures.

1574 **4.5.10 Issues with Mailing Lists**

1575 DKIM assumes that the email came from the MTA domain that generated the signature. This
1576 presents some problems when dealing with certain mailing lists. Often, MTAs that process
1577 mailing lists change the bodies of mailing list messages—for example, adding a footer with
1578 mailing list information or similar. Such actions are likely to invalidate DKIM signatures, unless
1579 for example, a message length is specified in the signature headers, and the additions come
1580 beyond that length.

1581 Fundamentally, mailing lists act as active mail parties. They receive messages from senders and
1582 resend them to recipients. Sometimes they send messages as they are received, sometimes the
1583 messages are bundled and sent as a single combined message, and sometimes recipients are able
1584 to choose their delivery means. As such, mailing lists should verify the DKIM signatures of
1585 incoming messages, and then re-sign outgoing messages with their own DKIM signature, made
1586 with the MTA’s public/private key pair. See [RFC6377], “DomainKeys Identified Mail (DKIM)
1587 and Mailing Lists,” also identified as IETF BCP 167, for additional discussion of DKIM and
1588 mailing lists.

1589 Additional assurance can be obtained by providing mailing lists with a role-based (i.e. not a
1590 named individual) S/MIME certificate and digitally signing outgoing. Such signatures will allow
1591 verification of the mailing list signature using S/MIME aware clients such as Microsoft Outlook,
1592 Mozilla Thunderbird, and Apple Mail. See Sections 2.4.2 and 4.7 for a discussion of S/MIME.
1593 Signatures are especially important for broadcast mailing lists that are sent with message-From:
1594 addresses that are not monitored, such as “do-not-reply” email addresses.

1595 **Security Recommendation 4-8:** Mailing list software should verify DKIM signatures on
1596 incoming mail and re-sign outgoing mail with new DKIM signatures.

1597 **Security Recommendation 4-9:** Mail sent to broadcast mailing lists from do-not-reply or
1598 unmonitored mailboxes should be digitally signed with S/MIME signatures so that recipients can
1599 verify the authenticity of the messages.

1600 As with SPF (subsection 4.2 above), DKIM may not prevent a spammer/advertiser from using a
1601 legitimately obtained domain to send unsolicited, DKIM-signed email. DKIM is used to provide
1602 assurance that the purported sender is the originator of the message, and that the message has not
1603 been modified in transit by an unauthorized intermediary.

1604 **4.5.11 Considerations for Enterprises When Using Cloud or Contracted Email Services**

1605 An enterprise that uses third party senders for email services needs to have a policy in place for
1606 DKIM key management. The nature of DKIM requires that the sending MTA have the private
1607 key in order to generate signatures while the domain owner may only have the public portion.
1608 This makes key management controls difficult to audit and or impossible to enforce.
1609 Compartmentalizing DKIM keys is one approach to minimize risk when sharing keying material
1610 between organizations.

1611 When using DKIM with cloud or contracted services, an enterprise should generate a unique key
1612 pair for each service. No private key should be shared between contracted services or cloud
1613 instances. This includes the enterprise itself, if email is sent by MTAs operated within the
1614 enterprise.

1615 **Security Recommendation 4-10:** A unique DKIM key pair should be used for each third
1616 party that sends email on the organization's behalf.

1617 Likewise, at the end of contract lifecycle, all DKIM keys published by the enterprise must be
1618 deleted or modified to have a blank `p=` field to indicate that the DKIM key has been revoked.
1619 This prevents the third party from continuing to send DKIM validated email.

1620 **4.6 Domain-based Message Authentication, Reporting and Conformance (DMARC)**

1621 SPF and DKIM were created so that email sending domain owners could give guidance to
1622 receivers about whether mail purporting to originate from them was valid, and thus whether it
1623 should be delivered, flagged, or discarded. Both SPF and DKIM offer implementation flexibility
1624 and different settings can have different effects at the receiver. However, neither SPF nor DKIM
1625 include a mechanism to tell receivers if SPF or DKIM are in use, nor do they have feedback
1626 mechanism to inform sending domain owners of the effectiveness of their authentication
1627 techniques. For example, if a message arrives at a receiver without a DKIM signature, DKIM
1628 provides no mechanism to allow the receiver to learn if the message is authentic but was sent
1629 from a sender that did not implement DKIM, or if the message is a spoof.

1630 DMARC [RFC7489] allows email sending domain owners to specify policy on how receivers
1631 can verify the authenticity of their email, how the receiver can handle email that fails to verify,
1632 and the frequency and types of report that receivers should send back. DMARC benefits
1633 receivers by removing the guesswork about which security protocols are in use, allowing more
1634 certainty in quarantining and rejecting inauthentic mail.

1635 To further improve authentication, DMARC adds a link between the domain of the sender with
1636 the authentication results for SPF and DKIM. In particular, receivers compare the domain in the
1637 message-From: address in the message to the SPF and DKIM results (if deployed) and the
1638 DMARC policy in the DNS. The results of this data gathering are used to determine how the mail
1639 should be handled. Thus, when an email fails SPF and DKIM verification, or the message-From:
1640 domain-part doesn't match the authentication results, the email can be treated as inauthentic
1641 according to the sending domain owners DMARC policy.

1642 DMARC also provides a mechanism that allows receivers to send reports to the domain owner
1643 about mail claiming to originate from their domain. These reports can be used to illuminate the
1644 extent to which unauthorized users are using the domain, and the proportion of mail received that
1645 is from the purported sender.

1646 **4.6.1 DMARC on the Sender Side**

1647 DMARC policies work in conjunction with SPF and/or DKIM, so a mail domain owner
1648 intending to deploy DMARC must deploy SPF or DKIM or (preferably) both. To deploy
1649 DMARC, the sending domain owner will publish SPF and/or DKIM policies in the DNS, and

1650 calculate a signature for the DKIM header of every outgoing message. The domain owner also
 1651 publishes a DMARC policy in the DNS advising receivers on how to treat messages purporting
 1652 to originate from the sender’s domain. The domain owner does this by publishing its DMARC
 1653 policy as a TXT record in the DNS¹²; identified by creating a **_dmarc** DNS record and publishing
 1654 it in the sending domain name. For example, the DMARC policy for “example.gov” would
 1655 reside at the fully qualified domain name **_dmarc.example.gov**.

1656 When implementing email authentication for a domain for the first time, a sending domain owner
 1657 is advised to first publish a DMARC RR with a “none” policy before deploying SPF or DKIM.
 1658 This allows the sending domain owner to immediately receive reports indicating the volume of
 1659 email being sent that purports to be from their domain. These reports can be used in crafting an
 1660 email authentication policy that reduces the risk of errors.

1661 Since the sending domain owner will be soliciting feedback reports by email from receivers, the
 1662 administrator should establish email addresses to receive aggregate and failure reports. As the
 1663 DMARC RR is easily discovered, the reporting inboxes will likely be subject to voluminous
 1664 unsolicited bulk email (i.e. spam). Therefore, some kind of abuse counter-measures for these
 1665 email in-boxes should be deployed.

1666 Even if a sending domain owner does not deploy SPF or DKIM records it may be useful to
 1667 deploy a DMARC record with policy **p=none** and a **rua** tag, to encourage receivers to send
 1668 aggregate reports about the use to which the sender’s domain is being put. This can help with
 1669 preliminary evaluation to determine whether a mail sender should mount SPF and DKIM
 1670 defenses.

1671 4.6.2 The DMARC DNS Record

1672 The DMARC policy is encoded in a TXT record placed in the DNS by the sending domain
 1673 owner. Similar to SPF and DKIM, the DMARC policy is encoded in a series of **tag=value** pairs
 1674 separated by semicolons. Common keys are:

1675 **Table 4-6: DMARC RR Tag and Value Descriptions**

Tag	Name	Description
v=	Version	Version field that must be present as the first element. By default the value is always DMARC1 .
p=	Policy	Mandatory policy field. May take values none or quarantine or reject . This allows for a gradually tightening policy where the sender domain recommends no specific action on mail that fails DMARC checks (p=none), through treating failed mail as suspicious (p=quarantine), to rejecting all failed mail (p=reject), preferably at the SMTP transaction stage.

¹² Example tool: <https://dmarcguide.globalcyberalliance.org/>

aspf=	SPF Policy	Values are "r" (default) for relaxed and "s" for strict SPF domain enforcement. Strict alignment requires an exact match between the message-From: address domain and the (passing) SPF check must exactly match the RFC envelope-From: address (i.e. the HELO address). Relaxed requires that only the message-From: and envelope-From: address domains be in alignment. For example, the envelope-From: address domain-part "smtp.example.org" and the message-From: address "announce@example.org" are in alignment, but not a strict match.
adkim=	DKIM Policy	Optional. Values are "r" (default) for relaxed and "s" for strict DKIM domain enforcement. Strict alignment requires an exact match between the message-From: domain in the message header and the DKIM domain presented in the "d=" DKIM tag. Relaxed requires only that the domain part is in alignment (as in aspf above).
fo=	Failure Reporting options	Optional. Ignore if a "ruf" argument below is not also present. Value 0 indicates the receiver should generate a DMARC failure report if all underlying mechanisms fail to produce an aligned "pass" result. Value 1 means generate a DMARC failure report if any underlying mechanism produces something other than an aligned "pass" result. Other possible values are "d" and "s": "d" means generate a DKIM failure report if a signature failed evaluation. "s" means generate an SPF failure report if the message failed SPF evaluation. These values are not exclusive and may be combined together in a colon-separated list.
ruf=		Optional. Lists a series of Universal Resource Indicators (URI's) (currently just "mailto:<emailaddress>") that list where to send failure feedback reports. This is for reports on message specific failures. Sending domain owners should use this argument sparingly, since it is used to request a report on a per-failure basis, which could result in a large volume of failure reports.
rua=		Optional list of URI's (like in ruf= above, using the "mailto:" URI) listing where to send aggregate feedback back to the sending domain owner. These reports are sent based on the interval requested using the "ri=" option below, with a default of 86400 seconds if not listed.

ri=	Reporting Interval	Optional with the default value of 86400 seconds (one day). The value listed is the reporting interval desired by the sending domain owner.
pct=	Percent	Optional with the default value of 100 (%). Expresses the percentage of a sending domain owner’s mail that should be subject to the given DMARC policy in a range from 0 to 100. This allows domain owners to ramp up their policy enforcement gradually and prevent having to commit to a rigorous policy before getting feedback on their existing policy. Note: this value must be an integer.
sp=	Subdomain Policy	Optional with a default value of none . Other values include the same range of values as the ‘ p= ’ argument. This is the policy to be applied to mail from all identified subdomains of the given DMARC RR. If a receiver fails to find a valid DMARC RR for a given sending domain, it will attempt to find a DMARC RR for a parent zone and apply a DMARC policy if the sp= tag is present.

1676

1677 Like SPF and DKIM, the DMARC record is actually a DNS TXT RR. Like all DNS information,
 1678 it should be signed using DNSSEC [RFC4033], [RFC4034], and [RFC4035] to prevent an
 1679 attacker from spoofing the DNS response and altering the DMARC check by a client.

1680 **4.6.3 Example of DMARC RR’s**

1681 Below are several examples of DMARC policy records using the above tags. The most basic
 1682 example is a DMARC policy that effectively does not assert anything and does not request the
 1683 receiver send any feedback reports, so it is, in effect, useless.

1684 `_dmarc.example.gov 3600 IN TXT “v=DMARC1; p=none;“`

1685 An agency that is preparing to deploy SPF and/or DKIM, or has deployed these technologies, but
 1686 may not be confident in their current policies may request aggregate reports from receivers, but
 1687 otherwise advises no specific action. The agency can do so by publishing a **p=none** policy as in
 1688 the example below.

1689 `_dmarc.example.gov 3600 IN TXT “v=DMARC1; p=none;
 1690 rua=reports@example.gov;“`
 1691

1692 An agency that has deployed SPF and DKIM and advises receivers to reject any messages that
 1693 fail these checks would publish a **p=reject** policy as in the example below. Here, the agency also
 1694 wishes to receive aggregate reports on a daily basis (the default).

1695 `_dmarc.example.gov 3600 IN TXT “v=DMARC1; p=reject;`

1696 **rua=reports@example.gov;“**

1697

1698 The agency in the process of deploying DKIM (but has confidence in their SPF policy) may wish
 1699 to receive feedback solely on DKIM failures, but does not wish to be inundated with feedback,
 1700 so requests that the policy be applied to a subset of messages received. In this case, the DMARC
 1701 policy would include the **fo=** option to indicate only DKIM failures are to be reported and a **pct=**
 1702 value of **10** to indicate that only 1 in 10 email messages should be subjected to this policy (and
 1703 subsequent reporting on a failure). Note that this is not a wise strategy in that it reduces the
 1704 enforcement policy and the completeness of reporting. The use of the **pct** value in values other
 1705 than 0 or 100 (i.e. none or full) limits DMARC effectiveness and usefulness of reporting. It is
 1706 also burdensome for receivers to choose that intermediate percentage of mail for testing.

1707 **_dmarc.example.gov 3600 IN TXT “v=DMARC1; p=none; pct=10; fo=d;**

1708 **ruf=reports@example.gov;“**

1709

1710 An agency with several subdomains may wish to have a single unified policy, in which case a
 1711 DMARC RR with the **sp=** tag is used. In this example, the domain has a policy to reject any mail
 1712 from a subdomain of example.gov that fails checks, while only quarantining email that failed
 1713 checks from the parent domain.

1714 **_dmarc.example.gov 3600 IN TXT “v=DMARC1; p=quarantine; sp=reject;**

1715 **rua=reports@example.gov;”**

1716

1717 **Security Recommendation 4-11:** Sending domain owners who deploy SPF and/or DKIM are
 1718 recommended to publish a DMARC record signaling to mail receivers the disposition expected
 1719 for messages purporting to originate from the sender’s domain.

1720 **4.6.4 DMARC on the Receiver Side**

1721 Receivers of email purporting to originate from a given domain will look up the SPF, DKIM and
 1722 DMARC records in the DNS and act on the policies encoded therein. The recommended
 1723 processing order per [RFC7489] is given below. Note that it is possible that some steps could be
 1724 done in parallel and local policy may alter the order of some steps (i.e. steps 2, 3 and 4).

- 1725 1. The receiver extracts the message-From: address from the message. This must contain a
 1726 single, valid address or else the mail is refused as an error.
- 1727 2. The receiver queries for the DMARC DNS record based on the message-From: address. If
 1728 none exists, terminate DMARC processing. This may include queries to any potential
 1729 parent zone of the sender.
- 1730 3. The receiver performs DKIM signature checks. If more than one DKIM signature exists
 1731 in the message, one must verify.
- 1732 4. The receiver queries for the sending domain's SPF record and performs SPF validation
 1733 checks.
- 1734 5. The receiver conducts Identifier Alignment checks between the message-From: and the
 1735 results of the SPF and DKIM records (if present). It does so by comparing the domain

1736 extracted from the message-From: (as in step 2 above) with the domain in the verified
 1737 SPF and/or DKIM verification steps. If there is a match with either the domain verified by
 1738 SPF or DKIM, then the DMARC Identifier Alignment check passes.
 1739 6. The receiver applies the DMARC policy found in the purported sender's DMARC record
 1740 unless it conflicts with the receiver's local policy. The receiver will also store the results
 1741 of evaluating each received message for the purpose of compiling aggregate reports sent
 1742 back to the domain owner (as specified in the **rua** tag).

1743 Note that local email processing policy may override a sending domain owner's stated DMARC
 1744 policy. The receiver should also store the results of evaluating each received message in some
 1745 persistent form for the purpose of compiling aggregate reports.

1746 Even if steps 2-5 in the above procedure yield no SPF or DKIM records to evaluate the message,
 1747 it is still useful to send aggregate reports based on the sending domain owner's DMARC
 1748 preferences, as it helps shape sending domain responses to spam in the system.

1749 **Security Recommendation 4-12:** Mail receivers who evaluate SPF and DKIM results of
 1750 received messages are recommended to dispose them in accordance with the sending domain's
 1751 published DMARC policy, if any. They are also recommended to initiate failure reports and
 1752 aggregate reports according to the sending domain's DMARC policies.

1753 **4.6.5 Policy and Reporting**

1754 DMARC can be seen as consisting of two components: a policy on linking SPF and DKIM
 1755 checks to the message-From: address, and a reporting mechanism. The reason for DMARC
 1756 reporting is so that domain owners can get feedback on their SPF, DKIM, Identifier Alignment
 1757 and message disposition policies so these can be made more effective. The DMARC protocol
 1758 specifies a system of aggregate reports sent by receivers on a periodic basis, and failure reports
 1759 sent on a message-by-message basis for email that fail some component part of the DMARC
 1760 checks. The specified form in which receivers send aggregate reports is as a compressed (zipped)
 1761 XML file based on the AFRF format [RFC6591], [RFC7489]¹³. Each aggregate report from a
 1762 mail receiver back to a particular domain owner includes aggregate figures for successful and
 1763 unsuccessful message authentications including:

- 1764 • The sending domain owner's DMARC policy for that interval (domain owners may
 1765 change policies and it is undetermined whether a receiver will respond based on the old
 1766 policy or the new policy).
- 1767 • The message disposition by the receiver (i.e. delivered, quarantined, rejected).
- 1768 • SPF result for a given SPF identifier.
- 1769 • DKIM result for a given DKIM identifier.
- 1770 • Whether identifiers are in alignment or not.

¹³ Appendix C of RFC 7489

- 1771 • Results classified by sender subdomain (whether or not a separate **sp** policy exists).
- 1772 • The sending and receiving domain pair.
- 1773 • The policy applied, and whether this is different from the policy requested.
- 1774 • The number of successful authentications.
- 1775 • Totals for all messages received.

1776 Based on the return flow of aggregate reports from the aggregation of all receivers, a domain
 1777 owner can build up a picture of the email being sent and how it appears to outside receivers. This
 1778 allows the domain owner to identify gaps in email infrastructure and policy and how (and when)
 1779 it can be improved. In the early stages of building up this picture, the sending domain should set
 1780 a DMARC policy of **p=none**, so the ultimate disposition of a message that fails some checks rests
 1781 wholly on the receiver's local policy. As DMARC aggregate reports are collected, the domain
 1782 owner will have a quantitatively better assessment of the extent to which the sender's email is
 1783 authenticated by outside receivers, and will be able to set a policy of **p=reject**, indicating that any
 1784 message that fails the SPF, DKIM and alignment checks really should be rejected via a SMTP
 1785 reply code signaling rejection, or silently discarding the message. From their own traffic analysis,
 1786 receivers can develop a determination of whether a sending domain owner's **p=reject** policy is
 1787 sufficiently trustworthy to act on.

1788 Failure reports from receivers to domain owners help debug and tune the component SPF and
 1789 DKIM mechanisms as well as alerting the domain owner that their domain is being used as part
 1790 of a phishing/spam campaign. Typical initial rollout of DMARC in an enterprise will include the
 1791 **ruf** tag with the values of the **fo** tag progressively modified to capture SPF debugging, DKIM
 1792 debugging or alignment debugging. Failure reports are expensive to produce, and bear a real
 1793 danger of providing a DDoS source back to domain owners, so when sufficient confidence is
 1794 gained in the integrity of the component mechanisms, the **ruf** tag may be dropped from DMARC
 1795 policy statements if the sending domain no longer wants to receive failure reports. Note however
 1796 that failure reports can also be used to alert domain owners about phishing attacks being
 1797 launched using their domain as the purported sender and therefore dropping the **ruf** tag is not
 1798 recommended.

1799 The same AFRF report format as for aggregate reports [RFC6591], [RFC7489] is also specified
 1800 for failure reports, but the DMARC standard updates it for the specificity of a single failure
 1801 report:

- 1802 • Receivers include as much of the message and message header as is reasonable to allow
 1803 the domain to investigate the failure.
- 1804 • Add an Identity-Alignment field, with DKIM and SPF DMARC-method fields as
 1805 appropriate (see above).
- 1806 • Optionally add a Delivery-Result field.
- 1807 • Add DKIM Domain, DKIM Identity and DKIM selector fields, if the message was DKIM
 1808 signed. Optionally also add DKIM Canonical header and body fields.
- 1809 • Add an additional DMARC authentication failure type, for use when some authentication
 1810 mechanisms fail to produce aligned identifiers.

1811 **4.6.6 Considerations for Agencies When Using Cloud or Contracted Email Services**

1812 The **rua** and **ruf** tags typically specify **mailto:** addresses in the sender’s domain. These reporting
 1813 addresses are normally assumed to be in the same domain as the purported sender, but not
 1814 always. Cloud providers and contracted services may provide DMARC report collection as part
 1815 of their service offerings. In these instances, the **mailto:** domain will differ from the sending
 1816 domain. To prevent DMARC reporting being used as a DoS vector, the owner of the **mailto:**
 1817 domain must signal its legitimacy by posting a DMARC TXT DNS record with the Fully
 1818 Qualified Domain Name (FQDN):

1819 *original-sender-domain._report._dmarc.mailto-domain*

1820 For example, an original message sent from **example.gov** is authenticated with a DMARC record:

1821 **_dmarc.example.gov. IN TXT "v=DMARC1; p=reject;**
 1822 **rua=mailto:reports.example.net"**

1823
 1824 The recipient then queries for a DMARC TXT RR at **example.gov._report._dmarc.example.net**
 1825 and checks the **rua** tag includes the value **rua=mailto:reports.example.net** to insure that the
 1826 address specified in the sending domain owner's DMARC record is the legitimate receiver for
 1827 DMARC reports.

1828 Note that, as with DKIM, DMARC records require the use of semicolons between tags.

1829 **4.6.7 Mail Forwarding**

1830 The message authentication devices of SPF, DKIM and DMARC are designed to work directly
 1831 between a sender domain and a receiver domain. The message envelope and RFC5322.From
 1832 address pass through a series of MTAs, and are authenticated by the receiver. The DKIM
 1833 signature, message headers and message body arrive at the receiver unchanged. The email system
 1834 has additional complexities as there are a variety of message forwarding activity that will very
 1835 often either modify the message, or change the apparent message-From: domain. For example,
 1836 user@example.gov sends a message to ourgroup@example.net, which is subsequently forwarded
 1837 to all members of the mail group. If the mail group software simply relays the message, the
 1838 envelope-From: address denoting the forwarder differs from the message-From: address,
 1839 denoting the original sender. In this case DMARC processing will rely on DKIM for
 1840 authentication. If the forwarder modifies the message-From: field to match the HELO of the
 1841 sending MTA (see Section 2.3.1), SPF may authenticate, but the modified header will make the
 1842 DKIM signature invalid. Table 4-2 below summarizes the various forwarding techniques and
 1843 their effect on domain-based authentication mechanisms:

1844 **Table 4-7: Common relay techniques and their impact on domain-based authentication**

Relay Technique	Typical Uses	Negatively Impacts
Aliases	Forwarding, many-to-one consolidation, vanity addresses	SPF

Re-sender	MUA level forwarding, inline forwarding	SPF & DKIM
Mailing Lists	Re-posting to a subscriber list, often with modifications to the message body (such as a footer identifying the mailing list).	SPF & DKIM results may lead to DMARC policy rejection and sender unsubscribe
Gateways	Unrestricted message re-writing, and forwarding	SPF & DKIM
Boundary Filters	Spam or malware filters that change/delete content of an email message	DKIM

1845

1846 One solution that can reduce the impact due to DKIM validation failures is the Authenticated
 1847 Receiver Chain (ARC)¹⁴. ARC is an extension of DKIM that generates a chain of possession
 1848 (called an ARC seal) as an email message moves from one MTA to another. ARC can be used to
 1849 give information about DKIM results during the chain of possession. ARC is not perfect because
 1850 a malicious actor can alter the ARC seal, so ARC should only be seen as a purported chain of
 1851 possession and a way mailing lists to operate without breaking DKIM signatures.

1852 Forwarding in general creates problems for DMARC results processing, and as of this writing,
 1853 universal solutions are still in development. There is a currently existing set of mitigations that
 1854 could be used by the mail relay and by the receiver, but would require modified MTA processing
 1855 from traditional SPF and DKIM processing:

- 1856 1. The mediator can alter the message-From: field to match the envelope-From:. In this case
 1857 the SPF lookup would be on the mediator's domain.
- 1858 2. After making the customary modifications, which break the originators DKIM signature,
 1859 the email relay can generate its own DKIM signature over the modified header and body.
 1860 Multiple DKIM signatures in a message are acceptable and DMARC policy is that at
 1861 least one of the signatures must authenticate to pass DMARC.

1862 It should also be noted that if one or the other (SPF or DKIM) authentication and domain
 1863 alignment checks pass, then the DMARC policy could be satisfied.

1864 At the receiver side, if a message fails DMARC and is bounced (most likely in the case where
 1865 the sender publishes a **p=reject** policy), then a mailing list may respond by unsubscribing the
 1866 recipient. Mailing list managers should be sensitive to the reasons for rejection and avoid
 1867 unsubscribing recipients if the bounce is due to message authentication issues. If the mailing list

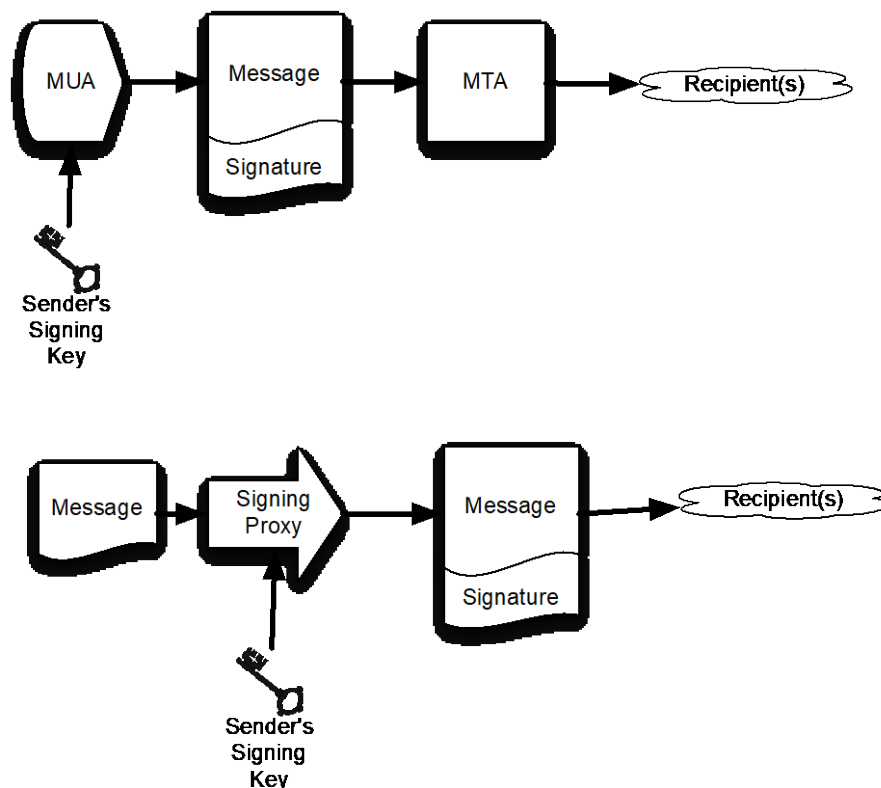

¹⁴ Authenticated Receiver Chain (ARC) Protocol. Work-in-Progress. <https://datatracker.ietf.org/doc/draft-ietf-dmarc-arc-protocol/>

1868 is in a domain where the recommendations in this document can be applied, then such mailing
1869 list managers should be sensitive to and accommodate DMARC authentication issues. In the case
1870 where the mailing list is outside the domain of influence, the onus is on senders and receivers to
1871 mitigate the effects of forwarding as best they can.

1872 **4.7 Authenticating Mail Messages with Digital Signatures**

1873 In addition to authenticating the sender of a message, the message contents can be authenticating
1874 with digital signatures. Signed email messages protect against phishing attacks, especially
1875 targeted phishing attacks, as users who have been conditioned to expect signed messages from
1876 co-workers and organizations are likely to be suspicious if they receive unsigned messages
1877 instructing them to perform an unexpected action [GAR2005]. For this reason, the Department of
1878 Defense requires that all e-mails containing a link or an attachment be digitally signed
1879 [DOD2009].

1880 Because it interoperates with existing PKI and most deployed software, S/MIME is the
1881 recommended format for digitally signing messages. Users of most email clients who receive
1882 S/MIME signed messages from organizations that use well-known CAs will observe that the
1883 message signatures are automatically validated, without the need to manually add or trust
1884 certificates for each sender. If users receive mail that originates from a sender that uses a non-
1885 public CA, then either the non-public CA must be added or else each S/MIME sender must be
1886 individually approved. Today, the US Government PIV [FIPS 201] cards are signed by well-
1887 known CAs, whereas the US Department of Defense uses CAs that are generally not trusted
1888 outside the Department of Defense. Thus, email signed by PIV cards will generally be validated
1889 with no further action, while email signed by DoD Common Access Cards will result in a
1890 warning that the sender's certificate is not trusted.

1891 **4.7.1 End-to-End Authentication Using S/MIME Digital Signatures**

1892

1893

Fig 4-1: Two models for sending digitally signed mail.

1894 Organizations can use S/MIME digital signatures to certify email that is sent within or external
 1895 to the organization. Because support for S/MIME is present in many modern mail clients¹⁵,
 1896 S/MIME messages that are signed with a valid digital signature will automatically validate when
 1897 they are displayed. This is particularly useful for messages that are designed to be read but not
 1898 replied to—for example, status reports and alerts that are sent programmatically, as well as
 1899 messages that are sent to announcement-only distribution lists.

1900 To send S/MIME digitally signed messages, organizations must first obtain a S/MIME certificate
 1901 where the sender matches the message-From: address that will be used to sign the messages.
 1902 Typically, this will be done with a S/MIME certificate and matching private key that corresponds
 1903 to the role, rather than to an individual.¹⁶ Once a certificate is obtained, the message is first
 1904 composed. Next, software uses both the S/MIME certificate and the private portion of their
 1905 S/MIME key pair to generate the digital signature. S/MIME signatures contain both the signature
 1906 and the signing certificate, allowing recipients to verify the signed message without having to
 1907 fetch the certificate from a remote server; the certificate itself is validated using PKI. Sending

¹⁵ Support for S/MIME is included in Microsoft Outlook, Apple Mail, iOS Mail, Mozilla Thunderbird, and other mail programs.

¹⁶ For example, DoDI 8520.02 (May 24, 2011), "Public Key Infrastructure (PKI) and Public Key (PK) Enabling," specifically allows certificates to be issued for groups, roles, information system, device, and code signing purposes, in addition to the issuance of certificates to eligible users.

1908 S/MIME signed messages thus requires either a MUA that supports S/MIME and the necessary
1909 cryptographic libraries to access the private key and generate the signature, or else an
1910 intermediate program that will sign the message after it is created but before it is delivered (Fig
1911 4-3).

1912 The receiver of the signed S/MIME message then uses the sender's public key (from the sender's
1913 attached X.509 certificate) and validates the digital signature. The receiver should also check to
1914 see if the senders certificate has a valid PKIX chain back to a root certificate the receiver trusts to
1915 further authenticate the sender. Some organizations may wish to configure MUAs to perform
1916 real-time checks for certificate revocation and an additional authentication check (See Section
1917 5.2.2.3).

1918 The principal barrier to using S/MIME for end-user digital signatures has been the difficulty of
1919 arranging for end-users to obtain S/MIME certificates. One approach is to issue S/MIME
1920 credentials in physical identity tokens, as is done with the US Government's PIV (Personal
1921 Identity Verification) cards [FIPS 201]. Individuals can obtain free S/MIME certificates from a
1922 number of online providers, who verify the individual's address with an email challenge.

1923 The principal barrier to using S/MIME for signing organizational email has been the lack of
1924 attention to the issue, since only a single certificate is required for signing mail and software for
1925 verifying S/MIME signatures is already distributed.

1926 **Security Recommendation 4-11:** Use S/MIME signatures for assuring message authenticity
1927 and integrity.

1928 **4.8 Recommendation Summary**

1929 **Security Recommendation 4-1:** Organizations are recommended to deploy SPF to specify
1930 which IP addresses are authorized to transmit email on behalf of the domain. Domains controlled
1931 by an organization that are not used to send email, for example Web only domains, should
1932 include an SPF RR with the policy indicating that there are no valid email senders for the given
1933 domain.

1934 **Security Recommendation 4-2:** Organizations should deploy DNSSEC for all DNS name
1935 servers and validate DNSSEC queries from all systems that receive email.

1936 **Security Recommendation 4-3:** Federal agency administrators shall only use keys with
1937 approved algorithms and lengths for use with DKIM.

1938 **Security Recommendation 4-4:** Administrators should insure that the private portion of the
1939 key pair is adequately protected on the sending MTA and that only the MTA software has read
1940 privileges for the key. Federal agency administrators should follow FISMA control SC-12
1941 [SP800-53] guidance with regards to distributing and protecting DKIM key pairs.

1942 **Security Recommendation 4-5:** Each sending MTA should be configured with its own
1943 private key and its own selector value, to minimize the damage that may occur if a private key is
1944 compromised.

- 1945 **Security Recommendation 4-6:** Organizations should deploy DNSSEC to provide
1946 authentication and integrity protection to the DKIM DNS resource records.
- 1947 **Security Recommendation 4-7:** Organizations should enable DNSSEC validation on DNS
1948 servers used by MTAs that verify DKIM signatures.
- 1949 **Security Recommendation 4-8:** Mailing list software should verify DKIM signatures on
1950 incoming mail and re-sign outgoing mail with new DKIM signatures.
- 1951 **Security Recommendation 4-9:** Mail sent to broadcast mailing lists from do-not-reply or
1952 unmonitored mailboxes should be digitally signed with S/MIME signatures so that recipients can
1953 verify the authenticity of the messages.
- 1954 **Security Recommendation 4-10:** A unique DKIM key pair should be used for each third
1955 party that sends email on the organization's behalf.
- 1956 **Security Recommendation 4-11:** Use S/MIME signatures for assuring message authenticity
1957 and integrity.

1958 **5 Protecting Email Confidentiality**

1959 **5.1 Introduction**

1960 Cleartext mail messages are submitted by a sender, transmitted hop-by-hop over a series of
 1961 relays, and delivered to a receiver. Any successful man-in-the-middle can intercept such traffic
 1962 and read it directly. Any bad actor, or organizationally privileged actor, can read such mail on
 1963 the submission or delivery systems. Email transmission security can be assured by encrypting the
 1964 traffic along the path. The Transport Layer Security protocol (TLS) [RFC5246] protects
 1965 confidentiality by encrypting bidirectional traffic and prevents passive monitoring. TLS relies on
 1966 public key cryptography and uses X.509 certificates [RFC5280] to encapsulate the public key,
 1967 and the Certificate Authority (CA) system to issue certificates and authenticate the origin of the
 1968 key.

1969 In recent years the CA system has become the subject of attack and has been successfully
 1970 compromised on several occasions.^{17,18} The DANE protocol [RFC6698] is designed to overcome
 1971 problems in the CA system by providing an alternative channel for authenticating public keys
 1972 using DNSSEC. The result is that the same trust relationships used to certify IP addresses can be
 1973 used to certify servers operating on those addresses. The mechanisms that combine to improve the
 1974 assurance of email transmission security are described in section 5.2.

1975 Encryption at the transport layer gives assurance of the integrity of data in transit, but senders
 1976 and receivers who want end-to-end assurance, (i.e. mailbox to mailbox) of confidentiality have
 1977 two alternative mechanisms for achieving this: S/MIME [RFC5750] and OpenPGP [RFC4880].
 1978 Both protocols are capable of signing (for authentication) and encryption (for confidentiality).
 1979 The S/MIME protocol is deployed to sign and/or encrypt message contents, using keys stored as
 1980 X.509 certificates and a PKI (See Section 2.4.2) while OpenPGP uses a different certificate and a
 1981 Web-of-Trust model for authentication of identities (See Section 2.4.3). Both of these protocols
 1982 have the issue of trustworthy certificate publication and discovery. These certificates can be
 1983 published through the DNS by a different implementation of the DANE mechanism for S/MIME
 1984 [RFC8162] and OpenPGP [RFC7929]. S/MIME and OpenPGP, with their strengthening by
 1985 DANE authentication are discussed below.

1986 **5.2 Email Transmission Security**

1987 Email proceeds towards its destination from a Message Submission Agent, through a sequence of
 1988 Message Transfer Agents, to a Message Delivery Agent, as described in Section 2. This
 1989 translates to the use of SMTP [RFC5321] for submission and hop-by-hop transmission and
 1990 IMAP [RFC3501] or POP3 [RFC1939] for final delivery into a recipient's mailbox. TLS
 1991 [RFC5246] can be used to protect email in transit for one or more hops, but intervening hops
 1992 may be under autonomous control, so a securely encrypted end-to-end path cannot be
 1993 guaranteed. This is discussed further in section 5.2.1. Opportunistic encryption over some

¹⁷ "Comodo SSL Affiliate The Recent RA Compromise," Phillip Hallam Baker, Comodo, March 15, 2011.
<https://blog.comodo.com/other/the-recent-ra-compromise/>

¹⁸ Peter Bright, "Independent Iranian hacker claims responsibility for Comodo hack," Ars Technica, March 28, 2011.
<http://arstechnica.com/security/2011/03/independent-iranian-hacker-claims-responsibility-for-comodo-hack/>

1994 portions of the path can provide “better-than-nothing” security. The use of STARTTLS
1995 [RFC3207] is a standard method for establishing a TLS connection. TLS has a secure handshake
1996 that relies on asymmetric encryption, to establish a secure session (using symmetric encryption).
1997 As part of the handshake, the server sends the client an X.509 certificate containing its public
1998 key, and the cipher suite and symmetric key are negotiated with a preference for the optimally
1999 strongest cipher that both parties support. SMTP clients have traditionally not verified the
2000 server’s certificate due to the lack of an appropriate mechanism to specify allowable certificates
2001 and certificate authorities. The newly adopted RFC 7672 [RFC 7672] rectifies this, by providing
2002 rules for applying the DANE protocol to SMTP servers. The use of DANE in conjunction with
2003 SMTP is discussed Section 5.2.4.

2004 From early 2015 there was an initiative in the IETF to develop a standard that allows for the
2005 implicit (default) use of TLS in email transmission. This goes under the title of Deployable
2006 Enhanced Email Privacy (DEEP). This scheme goes some steps beyond the triggering of
2007 STARTTLS, and is discussed further in Section 5.2.4.

2008 Ultimately, the entire path from sender to receiver will be protected by TLS. But this may consist
2009 of many hops between MTAs, each the subject of a separate transport connection. These are not
2010 compelled to upgrade to TLS at the same time, however in the patchwork evolutionary
2011 development of the global mail system, this cannot be completely guaranteed. There may be
2012 some MTAs along the route uncontrolled by the sender or receiver domains that have not
2013 upgraded to TLS. In the interim until all mail nodes are certifiably secure, the principle is that
2014 some incrementally improving security is better than no security, so opportunistic TLS (using
2015 DANE or other methods to validate certificates) should be employed at every possible hop.

2016 **5.2.1 TLS Configuration and Use**

2017 Traditionally, sending email begins by opening an SMTP connection over TCP and entering a
2018 series of cleartext commands, possibly even including usernames and passwords. This leaves the
2019 connection exposed to potential monitoring, spoofing, and various man-in-the-middle
2020 interventions. A clear improvement would be to open a secure connection that is encrypted so
2021 that the message contents cannot be passively monitored, and third parties cannot spoof message
2022 headers or contents. Transport Layer Security (TLS) offers the solution to these problems.

2023 TCP provides a reliable, flow-controlled connection for transmitting data between two peers.
2024 Unfortunately, TCP provides no built-in security. Transport connections carry all manner of
2025 sensitive traffic, including web pages with financial and sign-in information, as well as email
2026 messages. This traffic can only be secured through physical isolation, which is not possible on the
2027 Internet, or by encrypting the traffic.

2028 The Secure Sockets Layer (SSL) was developed to provide a standard protocol for encrypting
2029 TCP connections. SSL evolved into Transport Layer Security (TLS), the most recent version at
2030 the time of writing being Version 1.2 [RFC5246]. TLS negotiates a secure connection between
2031 initiator and responder (typically client and server) parties. The negotiation entails the exchange
2032 of the server’s certificate, and possibly the client’s certificate, and agreement on a cipher to use
2033 for encrypting the data. In essence, the protocol uses the public-private key pair: the public key
2034 in the server’s certificate, and the server’s closely held private key, to negotiate a symmetric

2035 algorithm and establish a key known to both parties, and with which both can encrypt, transmit
2036 and decrypt the application data. RFC 5246 Appendix A describes a range of permissible
2037 ciphers, and the parties agree on one from this set. This range of ciphers may be restricted on
2038 some hosts by local policy (such as only ciphers Approved for federal use). Data transmitted
2039 over the connection is encrypted using the negotiated session key. At the end, the connection is
2040 closed and the session key can be deleted (but not always, see below).

2041 Negotiating a TLS connection involves a significant time and processor load, so when the two
2042 parties have the need to establish frequent secure connections between them, a session
2043 resumption mechanism allows them to continue with the previously negotiated cipher, for a
2044 subsequent connection.

2045 TLS gains its security from the fact that the server holds the private key securely and the public
2046 key can be authenticated due to it being wrapped in an X.509 certificate that is guaranteed by
2047 some Certificate Authority. If the Certificate Authority is somehow compromised, there is no
2048 guarantee that the key in the certificate is truly the one belonging to the server, and a client may
2049 inadvertently negotiate with a man-in-the-middle. An investigation of what X.509 certificates
2050 are, how they work, and how they can be better secured, follows.

2051 **Security Recommendation 5-1:** NIST SP800-52 currently requires TLS 1.1 configured with
2052 FIPS based cipher suites as the minimum appropriate secure transport protocol. Organizations
2053 are recommended to migrate to TLS 1.2 with all practical speed.

2054 **5.2.2 X.509 Certificates**

2055 The idea of certificates as a secure and traceable vehicle for locating a public key, its ownership
2056 and use was first proposed by the Consultative Committee for International Telephony and
2057 Telegraphy (CCITT), now the International Telecommunications Union (ITU). The X.509
2058 specification was developed and brought into worldwide use as a result. In order to vest a
2059 certificate with some authority, a set of Certificate Authorities is licensed around the world as
2060 identifiable authentic sources. Each certificate hierarchy has a traceable root for authentication,
2061 and has specific traceable requirements for revocation, if that is necessary. As a certificate has a
2062 complex set of fields, the idea of a certificate profile has more recently come into play. X.509
2063 certificate formats are described in Section 5.2.2.1, their authentication in Section 5.2.2.2, and
2064 possible revocation in Section 5.2.2.3. The profile concept and a specific example are described
2065 in Section 5.2.2.4

2066 **5.2.2.1 X.509 Description**

2067 A trusted Certificate Authority (CA) is licensed to validate applicants' credentials, store each
2068 applicant's public key in a X.509 [RFC5280] structure, and digitally sign it with the CA's private
2069 key. Each applicant must first generate their own public and private key pair, save the private key
2070 securely, and wrap the public key into an X.509 request. The **openssl req** command is an example
2071 of how to do this on Unix/Linux systems with OpenSSL¹⁹ installed. Many CAs will generate a

¹⁹ <https://www.openssl.net/>

2072 certificate without receiving a request (in effect, generating the request themselves on the
 2073 customer's behalf). The resulting digitally encoded structure is transmitted to the CA, vetted
 2074 according to the CA's policy, and a certificate is issued. An example certificate is given below in
 2075 Figure 5-1, with salient fields described.

- 2076 • **Issuer:** The Certificate Authority that issued and signed this end-entity certificate. If the
 2077 issuer is a well-known reputable entity, its root certificate may be listed in host systems'
 2078 root certificate repository.
- 2079 • **Subject:** Sometimes referred to as the common name (CN). The entity to which this
 2080 certificate is issued by this CA. Here: **www.example.com**.
- 2081 • **Public Key:** (this field truncated for readability). This is the public key corresponding to
 2082 the private key held by the subject. Clients who receive the certificate in a secure
 2083 communication attempt extract the public key and use it for one of the stated key usages.
- 2084 • **X509v3 Key Usage:** The use of this certificate is restricted to digital signature, key
 2085 encipherment or key agreement. So an attempt to use it for data encipherment, for
 2086 example, should result in error.
- 2087 • **X509v3 Basic Constraints:** This certificate is an end certificate so the constraint is set to
 2088 **CA:FALSE**. It is not a CA certificate and its key cannot be used to sign downstream
 2089 certificates for other entities.
- 2090 • **X509v3 SubjectAltName:** Together with the common name in the Subject field, this
 2091 represents the binding of the public key to a domain. Any attempt by another domain to
 2092 transmit this certificate to try to establish a connection should result in failure to
 2093 authenticate and connection closure by the client.
- 2094 • **Signature Algorithm** (truncated for convenience). The signature generated by the CA
 2095 over this certificate, demonstrating the CA's authentication of the subject and its public
 2096 key.

2097 **Certificate:**

Fig 5-1: Example of X.509 Certificate

2156 5.2.2.2 X.509 Authentication

2157 The certificate given above is an example of an end certificate. Although it claims to be signed by
 2158 a well-known CA, anyone receiving this certificate in communication has the problem of
 2159 authenticating that signature. For this, full PKIX authentication back to the root certificate is
 2160 required. The CA issues a well-known self-signed certificate containing its public key. This is the
 2161 root certificate. A set of current root certificates, often numbering in the hundreds of certificates,
 2162 are held by individual browser developers and operating system suppliers as their set of trusted
 2163 root certificates. The process of authentication is the process of tracing the end certificate back to
 2164 a root certificate, through a chain of zero or more intermediate certificates.

2165 5.2.2.3 Certificate Revocation

2166 Every certificate has a period of validity typically ranging from 30 days up to a number of years.

2167 There may, however, be reasons to revoke a certificate prior to its expiration, such as the
 2168 compromise or loss of the private key [RFC5280]. The act of revocation is associated with the
 2169 CA publishing a certificate revocation list. Part of authenticating a certificate chain is perusing
 2170 the certificate revocation list (CRL) to determine if any certificate in the chain is no longer valid.
 2171 The presence of a revoked certificate in the chain should result in failure of authentication.
 2172 Among the problems of CRL management, the lack of real-time revocation checks leads to non-
 2173 determinism in the authentication mechanism. Problems with revocation led the IETF to develop
 2174 a real-time revocation management protocol, the Online Certificate Status Protocol (OCSP)
 2175 [RFC6960]. Mozilla has now taken the step to deprecate CRLs in favor of OCSP.

2176 **5.2.2.4 Certificate Profiles**

2177 The Federal Public Key Infrastructure (FPKI) Policy Authority has specified profiles (called the
 2178 FPIX profile) for two types of X.509 version 3 certificates that can be used for confidentiality
 2179 and integrity protection of federal email systems [FPKI-CERT]. The applicable certificate profile
 2180 is identified by the **KeyPurposeId** with value **id-kp-emailProtection (1.3.6.1.5.5.7.3.4)** and includes
 2181 the following:

- 2182 • End-Entity Signature Certificate Profile (Worksheet 5)
- 2183 • Key Management Certificate Profile (Worksheet 6)

2184 The overall FPIX profile is an instantiation of IETF's PKI profile developed by the PKIX
 2185 working group (and hence called the PKIX profile) [PKIX] with unique parameter settings for
 2186 Federal PKI systems. Thus, a FPIX certificate profile complements the corresponding PKIX
 2187 certificate profile. The following is a brief overview of the two applicable FPIX profiles
 2188 referenced above.

2189 **5.2.2.4.1 Overview of Key Management Certificate Profile**

2190 The public key of a Key Management certificate is used by a device (e.g., a Mail Transfer Agent
 2191 (MTA) in this context) to set up a session key (a symmetric key) with its transacting entity (e.g.,
 2192 the next-hop MTA in this context). The parameter values specified in the profile for this
 2193 certificate type, for some of the important fields are:

- 2194 • **Signature:** (of the certificate issuer) If the RSA is used as the signature algorithm for signing
 2195 the certificate by the CA, then the corresponding hash algorithms can only be either SHA-
 2196 256 or SHA-512.
- 2197 • **subjectPublicKeyInfo:** The allowed algorithms for the public key are RSA, Diffie-Hellman
 2198 (DH), Elliptic Curve (ECC), or the Key Exchange Algorithm (KEA).
- 2199 • **KeyUsage:** The keyEncipherment bit is set to 1 when the subject public key is RSA. The
 2200 KeyAgreement bit is set to 1 when the subject public key is Diffie-Hellman (DH), Elliptic
 2201 Curve (ECC), or Key Exchange Algorithm (KEA).
- 2202 • **KeyPurposeId:** Should include the value **id-kp-emailProtection (1.3.6.1.5.5.7.3.4)**
- 2203 • **subjectAltName:** Since this certificate is used by devices (as opposed to a human subject),
 2204 this field should contain the DNS name or IP Address.

2205 5.2.3 STARTTLS

2206 Unlike the World Wide Web, where the URL indicates that the secure variant (i.e., HTTPS) is in
2207 use, an email sender has only the email address, “**user@domain**”, to signal the destination and no
2208 way to direct that the channel must be secured. This is an issue not just on a sender-to-receiver
2209 basis, but also on a transitive basis, as SMTP is not an end-to-end protocol but instead a protocol
2210 that sends mail messages as a series of hops (i.e., MUA, MSA, multiple MTAs, etc.). Not only is
2211 there no way to signal that message submission must be secure, there is also no way to signal
2212 that any hop in the transmission should be secure. STARTTLS was developed to address some of
2213 the shortcomings of this system.

2214 RFC 3207 [RFC3207] describes an extension to SMTP that allows an SMTP client and server to
2215 use TLS to provide private, authenticated communication across the Internet. This gives SMTP
2216 agents the ability to protect some or all of their communications from eavesdroppers and
2217 attackers. If the client initiates the connection over a TLS-enabled port (e.g., port 465 was
2218 previously used for SMTP over SSL), the server advertises that the STARTTLS option is
2219 available to connecting clients. The client can then issue the STARTTLS command in the SMTP
2220 command stream, and the two parties proceed to establish a secure TLS connection. An
2221 advantage of using STARTTLS is that the server can offer SMTP service on a single port, rather
2222 than requiring separate port numbers for secure and cleartext operations. Similar mechanisms are
2223 available for running TLS over IMAP and POP protocols.

2224 When STARTTLS is initiated as a request by the server side, it may be susceptible to a
2225 downgrade attack, where a man-in-the-middle (MITM) is in place. In this case the MITM
2226 receives the STARTTLS request from the server reply to a connection request, and scrubs it out.
2227 The initiating client sees no TLS upgrade request and proceeds with an unsecured connection (as
2228 originally anticipated). Likewise, most MTAs default to sending messages over unencrypted
2229 TCP if certificate validation fails during the TLS handshake.

2230 Domains can signal their desire to receive email over TLS by publishing a public key in their
2231 DNS records using DANE (Section 5.2.4). Domains can also configure their email servers to
2232 reject mail that is delivered without being preceded by a TLS upgrade. Unfortunately, doing so at
2233 the present time may result in email not being delivered from clients that are not capable of TLS.
2234 Furthermore, mail that is sent over TLS will still be susceptible to MITM attacks unless the
2235 client verifies the that the server’s certificate matches the certificate that is advertised using
2236 DANE.

2237 If the client wants to ensure an encrypted channel, it should initiate the TLS request directly. This
2238 is discussed in Deployable Enhanced Email Privacy (DEEP), which is current work-in-progress
2239 in the IETF. If the server wishes to indicate that an encrypted channel should be used by clients,
2240 this can be indicated through an advertisement using DANE. If the end user wants security over
2241 the message content, then the message should be encrypted using S/MIME or OpenPGP, as
2242 discussed in Section 5.3.

2243 In this long transition period towards “TLS everywhere,” there will be security gaps where some
2244 MTA to MTA hop offers TCP only. In these cases, the receiving MTA suggestion of
2245 STARTTLS can be downgraded by the above MITM attack. In such cases, a channel thought

2246 secure by the end user can be compromised. A mitigating consolation is that opportunistic
 2247 security (i.e., use encryption when available) is better than no security. The more mail
 2248 administrators who actively deploy TLS, the fewer opportunities for effective MITM attacks. In
 2249 this way global email security improves incrementally.

2250 **5.2.3.1 Recommendations**

2251 **Security Recommendation 5-1:** TLS-capable servers should prompt clients to invoke the
 2252 STARTTLS command. TLS clients should attempt to use STARTTLS for SMTP, either initially,
 2253 or issuing the command when offered.

2254 **5.2.4 SMTP Security via Opportunistic DNS-based Authentication of Named Entities** 2255 **(DANE) Transport Layer Security (TLS)**

2256 For years, TLS has solved the problem of distributing public keys by using a certificate, signed
 2257 by some well-known Certification Authority (CA). Every browser developer and operating
 2258 system supplier maintains a list of CA root certificates as trust-anchors. These are called the
 2259 software's *root certificates* and are stored in the *root certificate store*. The PKIX procedure
 2260 allows the certificate recipient to trace a certificate back to the root. So long as the root certificate
 2261 remains trustworthy, and the authentication concludes successfully, the client can proceed with
 2262 the connection.

2263 Currently, there are hundreds of organizations acting as CAs on the Internet. If one CA
 2264 infrastructure or vetting procedure is compromised, the attacker can obtain the CA's private key,
 2265 or get issued certificates under a false name. There is no limitation of scope for the global PKI,
 2266 and a compromise of a single CA damages the integrity of the entire PKI system.

2267 Aside from a CA compromise, some CAs have engaged in poor security practices. For example,
 2268 some CAs have issued wildcard certificates that allow the holder to issue sub-certificates for any
 2269 domain or entity, anywhere in the world.²⁰

2270 DANE introduces mechanisms for domains to specify to clients which certificates should be
 2271 trusted for the domain. With DANE, a domain owner can publish DNS records that declare
 2272 clients should only trust certificates from a particular CA or that they should only trust only a
 2273 specific certificate or public key. Essentially, DANE replaces reliance on the security provided
 2274 by the CA system with reliance on the security provided by DNSSEC.

2275 DANE complements TLS. The TLS handshake yields an encrypted connection between a server
 2276 and a client and provides a server's X.509 certificate to the client.²¹ The TLS protocol does not
 2277 define how the certificate should be authenticated. Some implementations may do this as part of

²⁰ For examples of poor CA issuing practices involving sub-certificates, see "Bug 724929—Remove Trustwave Certificate(s) from trusted root certificates," February 7, 2012. https://bugzilla.mozilla.org/show_bug.cgi?id=724929. Also "Bug 698753—Entrust SubCA: 512-bit key issuance and other CPS violations; malware in wild," November 8, 2011. https://bugzilla.mozilla.org/show_bug.cgi?id=698753. Also "Revoking Trust in one CNNIC Intermediate Certificate," Mozilla Security Blog, March 23, 2015. <https://blog.mozilla.org/security/2015/03/23/revoking-trust-in-one-cnnic-intermediate-certificate/>

²¹ Also possibly from client to server.

2278 the TLS handshake, and some may leave it to the application to perform authentication.
2279 Whichever way is used, there is still a vulnerability: a CA can issue certificates for any domain,
2280 and if that a CA is compromised (as has happened more than once all too recently), an attacker
2281 can have it can issue a replacement certificate for any domain, and take control of a server's
2282 connections. Ideally, issuance and delivery of a certificate should be tied absolutely to the given
2283 domain. DANE creates this explicit link by allowing the server domain owner to create a TLSA
2284 resource record in the DNS [RFC6698] [RFC7671], which identifies the certificate, its public
2285 key, or a hash of either. When the client receives an X.509 certificate in the TLS negotiation, it
2286 looks up the TLSA RR for that domain and matches the TLSA data against the certificate as part
2287 of the client's certificate validation procedure.

2288 DANE has a number of usage models (called Certificate Usages) to accommodate users who
2289 require different forms of authentication. These Certificate Usages are given mnemonic names
2290 [RFC7218]:

- 2291 • With Certificate Usage DANE-TA(2), the TLSA RR designates a trust-anchor that issued
2292 one of the certificates in the PKIX chain. [RFC7671] requires that DANE-TA(2) trust
2293 anchors be included in the server "certificate message" unless the entire certificate is
2294 specified in the TLSA record (i.e., usage 2 0 0, indicating the TLSA RR contains a local
2295 root certificate).
- 2296
- 2297 • With Certificate Usage DANE-EE(3), the TLSA RR matches an end-entity, or leaf
2298 certificate.
- 2299
- 2300 • Certificate Usages PKIX-TA(0) and PKIX-EE(1) should not be used for opportunistic
2301 DANE TLS encryption [RFC 7672]. This is because, outside of web browsers, there is no
2302 authoritative list of trusted certificate authorities, and PKIX-TA(0) and PKIX-EE(1)
2303 require that both the client and the server have a prearranged list of mutually trusted CAs.

2304 In DANE-EE(3) the server certificate is directly specified by the TLSA record. Thus, the
2305 certificate may be self-issued, or it may be issued by a well-known CA. The certificate may be
2306 current or expired. Indeed, operators may employ either a public or a private CA for their DANE
2307 certificates and publish a combination of "3 1 1" and "2 1 1" TLSA records, both of which
2308 should match the server chain and be monitored. This allows clients to verify the certificate using
2309 either DANE or the traditional Certificate Authority system, significantly improving reliability.

2310 Secure SMTP communications involves additional complications because of the use of mail
2311 exchanger (MX) and canonical name (CNAME) DNS RRs, which may cause mail to be routed
2312 through intermediate hosts or to final destinations that reside at different domain names. [RFC
2313 7671] and [RFC7672] describe a set of rules that are to be used for finding and interpreting
2314 DANE policy statements.

2315 As originally defined, TLS did not offer a client the ability to specify a particular hostname when
2316 connecting to a server; this was a problem in the case where the server offers multiple virtual
2317 hosts from one IP address, and there was a desire to associate a single certificate with a single
2318 hostname. [RFC6066] defines a set of extensions to TLS that include the Server Name Indication
2319 (SNI), allowing a client to specifically reference the desired server by hostname, and the server

2320 can respond with the correct certificate.

2321 [RFC7671] and [RFC7672] require the client to send SNI, just in case the server needs this to
 2322 select the correct certificate. There is no obligation on the server to employ virtual hosting, or to
 2323 return a certificate that matches the client's SNI extension. There is no obligation on the client to
 2324 match anything against the SNI extension. Rather, the requirement on the client is to support at
 2325 least the TLSA base domain as a reference identifier for the peer identity when performing name
 2326 checks (matching against a TLSA record other than DANE-EE(3)). With CNAME expansion
 2327 either as part of MX record resolution or address resolution of the MX exchange, additional
 2328 names must be supported as described in [RFC7671] and [RFC7672].

2329 A DANE matching condition also requires that the connecting server match the SubjectAltName
 2330 from the delivered end certificate to the certificate indicated in the TLSA RR. DANE-EE
 2331 authentication allows for the server to deliver a self-signed certificate. In effect, DANE-EE is
 2332 simply a vehicle for delivering the public key. Authentication is inherent in the trust provided by
 2333 DNSSEC, and the SNI check is not required.

2334 **5.2.5 SMTP MTA Strict Transport Security (MTA-STS)**

2335 Some email providers regard the requirement that DANE records be secured with DNSSEC as a
 2336 major barrier to deployment. As an alternative, they have proposed SMTP Strict Transport
 2337 Security²², which relies on records that are announced via DNS but authenticated using
 2338 information distributed via HTTPS. The goal of MTA-STS is the same as DANE: to have a way
 2339 for a receiving MTA to publish its TLS policy and mitigate Man-in-the-Middle (MITM)
 2340 spoofing. SMA-STS can be used with DANE, as neither method precludes the use of the other.

2341 MTA-STS works by publishing both a special TXT RR in the DNS and a policy document at a
 2342 Well-Known URL. The client obtains both artifacts before attempting to establish a connection
 2343 to the receiving domain’s mail servers.

2344 **5.2.5.1 The MTA-STS DNS Resource Record**

2345 The receiving domain administrator generates a MTA-STS policy RR (a TXT Text RR) with the
 2346 following tag:value pairs (separated by “;”):

2347 **Table 5-1: MTA-STS Resource Record Tags and Descriptions**

Tag	Descriptions
v=	Version of MTA-STS in use. Currently, the only defined value is STSv1
id=	A string used to indicate policy instance. Used to signal to clients that the receiver’s policy has changed. It must be changed every

²² SMTP Strict Transport Security. Work in progress <https://datatracker.ietf.org/doc/draft-ietf-uta-mta-sts/>

	time there is a policy update on the receiver’s side.
--	---

2348

2349 The MTA-STS RR is published as a TXT RR using the receiving domain with **_mta-sts**
 2350 prepended. For example, if the receiving domain is **example.gov**, the MTA-STS RR is:

2351 **_mta-sts.example.gov IN TXT “v=STSV1; id=20170101000000Z”**

2352 **5.2.5.2 The MTA-STS Policy**

2353 The receiver then published a detailed policy document at a well-known URL consisting of the
 2354 domain with **mta-sts** prepended and **.well-known/mta-sts.txt** as the path. So, in the example
 2355 above, the URL containing the MTA-STS policy for **example.gov** would be found at:

2356 **https://mta-sts.example.gov/.well-known/mta-sts.txt**

2357 The policy must only be accessible via HTTPS and contains a plain/text resource used by the
 2358 client to connect to the receiver. The document contains tag:value pairs, separated by newlines.
 2359 The tags are:

2360 **Table 5-2: MTA-STS Policy Tags and Descriptions**

Tag	Description
version=	The version of MTA-STS in use by the receiver. Currently, the only defined value is STSV1
mode=	The requested behavior of clients if a TLS validation failure or MX matching failure occurs. Defined values are enforce , meaning a client should reject the connection, report , meaning a client should stop the connection and send a TLS failure report (see Section XX) and none , meaning a client should continue with the connection.
mx=	A hostname of a mail receiver that should be present (as common name or subject alternative name) in any received X.509 server certificates sent during a TLS handshake. A receiver’s policy resource may contain multiple mx= tags, each on a separate line.
max_age=	Maximum lifetime of a policy (in seconds). Used as a time to live for a cached policy.

	<p>Clients should recheck the receiver’s MTA-STS URL for a possible updated policy after the max_age has elapsed.</p>
--	--

2361

2362 An example MTA-STS policy for **example.gov** may look like the following (found at the URL
2363 above):

```

2364     version: STSv1
2365     mode: enforce
2366     mx: mail1.example.gov.
2367     mx: mail2.example.gov.
2368     max_age:86400
    
```

2369

2370 In the above, **example.gov** lists two mail servers for the domain (**mail1.example.gov** and
2371 **mail2.example.gov**). The domain also sets its policy to enforce, meaning that if a client sees a
2372 server certificate that lacks **mail1.example.gov** or **mail2.example.gov**, or encounters some other
2373 PKIX validation failure, it is to reject the connection.

2374 An MTA-STS compliant sender first checks for the presence of an MTA-STS policy at the
2375 receiver domain. First by checking its cache to see if an earlier discovered policy was found, or
2376 by looking in the DNS for the MTA-STS DNS RR. If it is a newly discovered policy, the client
2377 first gets the policy over HTTPS, then attempts to connect to each candidate MX listed in order
2378 in the policy. For each receiving mail server, the sender attempts to connect via STARTTLS,
2379 and validates the receiver’s server certificate. If successful, the message is delivered. If not, the
2380 sender moves on to the next mail server listed in the policy. If none of the connections are
2381 successful, the sender does not deliver the message.

2382 At the time of writing, there are no publicly available MTA-STS implementations, and only a
2383 single MTA-STS Internet draft has been posted. Therefore, it is not possible for organizations to
2384 deploy MTA-STS aware clients at the present time.

2385 **5.2.6 Comparing DANE and MTA-STS**

2386 Both DANE and MTA-STS were designed to assist opportunistic encryption and combat passive
2387 monitoring of SMTP connections. Receiving domains can support both if desired, to support all
2388 clients. Senders can implement both as well, as the current MTA-STS spec states that DANE
2389 DNSSEC responses take precedence. The basic merits of both are summarized in the table
2390 below:

2391

Table 5-3: Comparing DANE and MTA-STS

	DANE	MTA-STS
DNS RRType used	TLSA RRs	TXT RRs
Client Requirements	DNSSEC	HTTPS

CA scoping?	Yes	No
PKIX required?	No always	Yes
Self-Signed certificates acceptable?	Yes (when using CU=3)	No
Failure reporting to receiver?	No	Yes
Client behavior on failure	Close connection	Depends on policy

2392

2393 **Security Recommendation 5-2:** Receiving domains should implement protocols to signal
 2394 TLS usage to clients. Receivers should implement DANE, MTA-STS (or both) for all mail
 2395 servers listed in the domains MX Resource Record set.

2396 **Security Recommendation 5-3:** As federal agency use requires certificate chain
 2397 authentication against a known CA, Certificate Usage DANE-TA(2) is recommended when
 2398 deploying DANE to specify the CA that the agency has chosen to employ. Agencies should also
 2399 publish a DANE-EE(3) RR alongside the DANE-TA(2) RR for increased reliability. In both
 2400 cases the TLSA record should use a selector of SPKI(1) and a Matching field type of SHA2-
 2401 256(1), for parameter values of “3 1 1” and “2 1 1” respectively.

2402 5.2.7 Reporting TLS Errors to Senders

2403 Currently, there is no way for a MTA to report TLS failures to a receiving domain. If a sending
 2404 MTA cannot establish a TLS protected connection, there is no automated signaling to the
 2405 receiver as to the nature of the failure, only the receiver’s own logs. Previously, most MTAs
 2406 would simply continue to connect without TLS and deliver the mail. However, with options
 2407 such as Require TLS (see Section 7.3.2) and MTA-STS (Section 5.2.5), TLS failures will cause
 2408 more failures in delivery.

2409 There is work in progress²³ to have a standard way to report TLS failures back to receivers. The
 2410 concept is similar to DMARC (see Section 4.6) where receivers send failure reports back to
 2411 senders, only here senders send the failure report. The specification includes the report format as
 2412 well as how to signal reporting over SMTP or HTTPS. HTTPS is given as an option for senders
 2413 that wish to use a secure channel but believe SMTP over TLS will not work. Also like DMARC,
 2414 the location (via email or HTTPS) where reports should be sent are published in a DNS TXT
 2415 resource record that the sender can query for in the receiver’s domain. Here the TXT RR has a
 2416 well-known string `_smtp-tlsrpt` prepended and using the following tag:value pairs:

²³ *SMTP TLS Reporting*. Work in Progress <https://datatracker.ietf.org/doc/draft-ietf-uta-smtp-tlsrpt/>

2417

Table 5-3: TLS Reporting Value Tags and Descriptions

Tag	Description
v=	The version string. Default is TLSRPTv1
rua=	How the receiver wishes to have reports submitted. Options are mailto: (for email) or https (for a URI to post reports).

2418

2419 An example TLS reporting RR is given below for **example.gov**:

2420 `_smtp-tlsrpt.example.gov IN TXT`
 2421 `"v=TLSRPTv1;rua=https://reporttls.example.gov/reports"`
 2422

2423 Indicating that TLS failure reports when connecting to **example.gov** mail receivers should be sent
 2424 to the URI listed in the **rua** tag. A reporting RR may have multiple values in the **rua** tag,
 2425 indicating several alternative means to send reports.

2426 **5.2.8 Deployable Enhanced Email Privacy (DEEP)**

2427 STARTTLS is an opportunistic protocol. A client may issue the STARTTLS command to initiate
 2428 a secure TLS connection; the server may support it as a default connection, or may only offer it
 2429 as an option after the initial connection is established.

2430 Deployable Enhanced Email Privacy (DEEP)²⁴ is an IETF work-in-progress that proposes a
 2431 security improvement to this protocol by advocating that clients initiate TLS directly for POP,
 2432 IMAP or SMTP submission. Enterprises should also use the DNS service location RRType (SRV
 2433 RR) to allow for MUAs to identify MTAs/MSAs and automate TLS configuration for mail
 2434 retrieval (i.e., IMAP or POP3) and mail submission (i.e., SMTP) [RFC6186]. This work proposes
 2435 a confidence level that indicates an assurance of confidentiality between a given sender domain
 2436 and a given receiver domain. This aims to provide a level of assurance that current usage does
 2437 not.

2438 DEEP is a new specification, but many of the components discussed are previously specified and
 2439 have been available in implementations for many years. Until DEEP is fully deployed the use of
 2440 STARTTLS is recommended for servers to signal to clients that TLS is preferred. In the future,
 2441 protocol designs should adhere to the principle of client initiation of TLS for email connections.

2442 **5.3 Email Content Security**

2443 End users and their institutions have an interest in rendering the contents of their messages

²⁴ *Cleartext Considered Obsolete: Use of TLS for Email Submission and Access*. Work in Progress
<https://datatracker.ietf.org/doc/draft-ietf-uta-email-deep/>

2444 completely secure against unauthorized eyes. They can take direct control over message content
2445 security using either S/MIME [RFC5751] or OpenPGP [RFC4880]. In each of these protocols,
2446 the sender signs a message with a private key, and the receiver authenticates the signature with
2447 the public key obtained (somehow) from the sender. Signing provides a guarantee of the message
2448 source, but any man in the middle can use the public key to decode and read the signed message.
2449 For proof against unwanted readers, the sender encrypts a message with the recipient's public
2450 key or with a generated symmetric key that is encrypted with the receiver's public key which is
2451 obtained (somehow) from the receiver. The receiver decrypts the message with the corresponding
2452 private key, or a symmetric key encrypted with the recipient's public key, and the message
2453 content is kept confidential from mailbox to mailbox. Both S/MIME and OpenPGP are protocols
2454 that facilitate signing and encryption, but secure open distribution of public keys is still a hurdle.
2455 Two recent DANE protocols have been proposed to address this. The SMIMEA (for S/MIME
2456 certificates) and OPENPGPKEY (for OpenPGP keys) initiatives specify new DNS RR types for
2457 storing email end user key material in the DNS. S/MIME and SMIMEA are described in
2458 subsection 5.3.1, while OpenPGP and OPENPGPKEY are described in subsection 5.3.2.

2459 **5.3.1 S/MIME and SMIMEA**

2460 S/MIME is a protocol that allows email users to authenticate messages by digitally signing with
2461 a private key, and including the public key in an attached certificate. The recipient of the message
2462 performs a PKIX validation on the certificate, authenticating the message's originator. On the
2463 encryption side, the S/MIME sender typically encrypts the message text using a generated
2464 symmetric key, which is encrypted in turn with the public key of the recipient, which was
2465 previously distributed using some other, out of band, method. Within an organization it is
2466 common to obtain a correspondent's S/MIME certificate from an LDAP directory server.
2467 Another way to obtain a S/MIME certificate is by exchanging digitally signed messages.

2468 S/MIME had the advantage of being based on X.509 certificates, allowing existing software and
2469 procedures developed for the PKI to be used for email. Hence, where the domain-owning
2470 enterprise has an interest in securing the message content, S/MIME is preferred.

2471 The Secure/Multipurpose Internet Mail Extensions (S/MIME) [RFC5751] describes a protocol
2472 that will sign, encrypt or compress some, or all, of the body contents of a message. Signing is
2473 done using the sender's private key, while key encipherment is done with the recipient's known
2474 public key. Message encryption using the data encryption key, signing and compression can be
2475 done in any order and any combination. The operation is applied to the body, not the RFC 5322
2476 headings of the message. In the signing case, the certificate containing the sender's public key is
2477 also attached to the message.

2478 The receiver uses the associated public key to authenticate the digital signature over the message,
2479 demonstrating proof of origin and non-repudiation. The usual case is for the receiver to
2480 authenticate the supplied certificate using PKIX back to the Certificate Authority. Users who
2481 want more assurance that the key supplied is bound to the sender's domain can deploy the
2482 SMIMEA mechanism [RFC8162] in which the certificate and key can be independently retrieved
2483 from the DNS and authenticated per the DANE mechanism, similar to that described in Sub-
2484 section 5.2.5, above. The user who wants to encrypt a message retrieves the receiver's public

2485 key: which may have been sent on a prior signed message²⁵. If no prior signed message is at
 2486 hand, or if the user seeks more authentication than PKIX, then the key can be retrieved from the
 2487 DNS in an SMIMEA record. The receiver decrypts the data encryption key using the
 2488 corresponding private key, decrypts the message using the newly decrypted key and reads or
 2489 stores the message as appropriate.

2490

2491

2492

Fig 2-4: Sending an Encrypted Email

2493 To send an S/MIME encrypted message (Fig 2-4) to a user, the sender must first obtain the
 2494 recipient's X.509 certificate and use the certificate's public key, generate a data encryption key,
 2495 and use it to encrypt the composed message. In this case the sender must possess the recipient's
 2496 certificate before sending the message.

2497 An enterprise looking to use S/MIME to provide email confidentiality will need to obtain or
 2498 produce credentials for each end user in the organization. An organization can generate its own
 2499 root certificate and give its members a certificate generated from that root, or purchase
 2500 certificates for each member from a well-known Certificate Authority (CA).

2501 Using S/MIME for end-user encryption is further complicated by the need to distribute each end-
 2502 users' certificate to potential senders. Traditionally this is done by having correspondents
 2503 exchange email messages that are digitally signed that includes the sender's encryption
 2504 certificate, but not encrypted. Alternatively, organizations can configure LDAP servers to make
 2505 S/MIME public keys available as part of a directory lookup; mail clients such as Outlook and
 2506 Apple Mail can be configured to query LDAP servers for public keys necessary for message
 2507 encryption.

2508 5.3.1.1 S/MIME Recommendations

2509 Official use requires certificate chain authentication against a known Certificate Authority.

2510 Current MUAs use S/MIME private keys to decrypt the data encryption key that was used to
 2511 encrypt the email message each time that it is displayed, but leave the message encrypted in the

²⁵ The use of one key pair for both digital signatures and data encryption is not recommended, but very common.

2512 email store. This mode of operation is not recommended, as it forces the recipient of the
2513 encrypted email to maintain their private key indefinitely. Instead, the email should be decrypted
2514 prior to being stored in the mail store. The mail store, in turn, should be secured using an
2515 appropriate cryptographic technique (for example, disk encryption), extending protection to both
2516 encrypted and unencrypted email. If it is necessary to store mail encrypted on the mail server (for
2517 example, if the mail server is outside the control of the end-user's organization), then the
2518 messages should be re-encrypted with a changeable session key on a message-by-message basis.

2519 Where the DNS performs canonicalization of email addresses, a client requesting a hash encoded
2520 OPENPGPKEY or SMIMEA RR shall perform no transformation on the left part of the address
2521 offered, other than UTF-8 and lower-casing. This is an attempt to minimize the queries needed to
2522 discover an S/MIME certificate in the DNS for newly learned email addresses and allow for the
2523 initial email to be sent encrypted (if desired).

2524 5.3.2 OpenPGP and OPENPGPKEY

2525 OpenPGP [RFC4880] is a proposed Internet Standard for providing authentication and
2526 confidentiality for email messages. Although similar in purpose to S/MIME, OpenPGP is
2527 distinguished by using message and key formats that are built on the "Web of Trust" model (see
2528 Section 2.4.3).

2529 The OpenPGP standard is implemented by PGP-branded software from Symantec²⁶ and by the
2530 open source GNU Privacy Guard.²⁷ These OpenPGP programs have been widely used by
2531 activists and security professionals for many years, but have never gained a widespread
2532 following among the general population owing to usability programs associated with installing
2533 the software, generating keys, obtaining the keys of correspondents, encrypting messages, and
2534 decrypting messages. Academic studies have found that even "easy-to-use" versions of the
2535 software that received good reviews in the technical media for usability were found to be not
2536 usable when tested by ordinary computer users. [WHITTEN1999]

2537 Key distribution was an early usability problem that OpenPGP developers attempted to address.
2538 Initial efforts for secure key distribution involved *key distribution parties*, where all participants
2539 are known to and can authenticate each other. This method does a good job of authenticating
2540 users to each other and building up webs of trust, but it does not scale at all well, and it is not
2541 greatly useful where communicants are geographically widely separated.

2542 To facilitate the distribution of public keys, a number of publicly available key servers have been
2543 set up and have been in operation for many years. Among the more popular of these is the pool
2544 of SKS keyservers²⁸. Users can freely upload public keys on an opportunistic basis. In theory,
2545 anyone wishing to send a PGP user encrypted content can retrieve that user's public key from the
2546 SKS server, use it to encrypt a generated data encryption key used to encrypt the message, and
2547 send it. However, there is no authentication of the identity of the key owners; an attacker can

²⁶ <http://www.symantec.com/products-solutions/families/?fid=encryption>

²⁷ <https://www.gnupg.org/>

²⁸ An incomplete list of well-known keyservers can be found at <https://www.sks-keyservers.net>

2548 upload their own key to the key server, then intercept the email sent to the unsuspecting user.

2549 A renewed interest in personal control over email authentication and encryption has led to further
2550 work within the IETF on key sharing, and the DANE mechanism [RFC7929] is being adopted to
2551 place a domain and user's public key in an OPENPGPKEY record in the DNS. Unlike
2552 DANE/TLS and SMIMEA, OPENPGPKEY does not use X.509 certificates, or require full PKIX
2553 authentication as an option. Instead, full trust is placed in the DNS records as certified by
2554 DNSSEC: The domain owner publishes a public key and minimal "certificate" information. The
2555 key is available for the receiver of a signed message to authenticate, or for the sender of a
2556 message to encrypt a data encryption key.

2557 **Security Recommendation 5-4:** For Federal use, OpenPGP is not preferred for message
2558 confidentiality. The use of S/MIME with a certificate signed by a known CA is preferred.

2559 5.3.2.1 Recommendations

2560 Where an institution requires signing and encryption of end-to-end email, S/MIME is preferred
2561 over OpenPGP. Like the S/MIME discussion above, if used, the email should be decrypted prior
2562 to being stored in the mail store. The mail store, in turn, should be secured using an appropriate
2563 cryptographic technique (for example, disk encryption), extending protection to both encrypted
2564 and unencrypted email. If it is necessary to store mail encrypted on the mail server (for example,
2565 if the mail server is outside the control of the end-user's organization), then the messages should
2566 be re-encrypted with a changeable session key on a message-by-message basis. In addition,
2567 where the DNS performs canonicalization of email addresses, a client requesting a hash encoded
2568 OPENPGPKEY or SMIMEA RR shall perform no transformation on the left part of the address
2569 offered, other than UTF-8 and lower-casing.

2570 5.4 Security Recommendation Summary

2571 **Security Recommendation 5-1:** TLS-capable servers should prompt clients to invoke the
2572 STARTTLS command. TLS clients should attempt to use STARTTLS for SMTP, either initially,
2573 or issuing the command when offered.

2574 **Security Recommendation 5-2:** Receiving domains should implement protocols to signal
2575 TLS usage to clients. Receivers should implement DANE, MTA-STS (or both) for all mail
2576 servers listed in the domains MX Resource Record set.

2577

2578 **Security Recommendation 5-3:** Official use of digitally signed/encrypted email requires
2579 certificate chain authentication against a known CA and using DANE-TA Certificate Usage
2580 values when deploying DANE.

2581 **Security Recommendation 5-4:** Do not use OpenPGP for message confidentiality. Instead,
2582 use S/MIME with a certificate that is signed by a known CA.

2583 6 Reducing Unsolicited Bulk Email

2584 6.1 Introduction

2585 Unsolicited Bulk Email (UBE) has an analogy with “beauty”, in that it is often in the eye of the
2586 beholder. To some senders, it is a low-cost marketing campaign for a valid product or service. To
2587 many receivers and administrators, it is a scourge that fills up message inboxes and can be a
2588 vector for criminal activity or malware. Both of these views can be true, as the term Unsolicited
2589 Bulk Email (or *spam*, as it is often called) comprises a wide variety of email received by an
2590 enterprise.

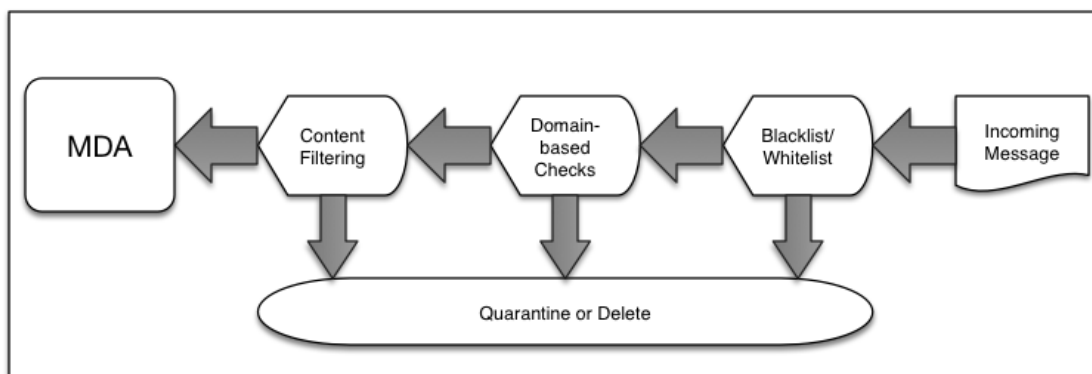

2591 6.2 Why an Organization May Want to Reduce Unsolicited Bulk Email

2592 While some unsolicited email is from legitimate marketing firms and may only rise to the level
2593 of being a nuisance, it can also lead to increased resource usage in the enterprise. UBE can fill up
2594 user inbox storage, consume bandwidth in receiving email and consume end users' time as they
2595 sort through and delete unwanted email. However, some UBE may rise to the level of being a
2596 legitimate threat to the organization in the form of fraud, illegal activity, or the distribution of
2597 malware.

2598 Depending on the organization's jurisdiction, UBE may include advertisements for goods or
2599 services that are illegal. Enterprises or organizations may wish to limit their employees' (and
2600 users') exposure to these offers. Other illegitimate UBE are fraud attempts aimed at the users of a
2601 given domain and used to obtain money or private information. Lastly, some UBE is simply a
2602 Trojan horse aimed at trying to infiltrate the enterprise to install malware.

2603 6.3 Techniques to Reduce Unsolicited Bulk Email

2604 There are a variety of techniques that an email administrator can use to reduce the amount of
2605 UBE delivered to the end users' inboxes. Enterprises can use one or multiple technologies to
2606 provide a layered defense against UBE since no solution is completely effective against all UBE.
2607 Administrators should consider using a combination of tools for processing incoming, and
2608 outgoing email.

2609

2610

Fig 6-1 Inbound email "pipeline" for UBE filtering

2611 These techniques can be performed in serial as a "pipeline" for both incoming and outgoing
 2612 email [REFARCH]. Less computationally expensive checks should be done early in the pipeline
 2613 to prevent wasted effort later. For example, a UBE/SMTP connection that would be caught and
 2614 refused by a blacklist filter should be done before more computationally expensive content
 2615 analysis is performed on an email that will ultimately be rejected or deleted. In Figure 6-1, an
 2616 example pipeline for incoming email checks is given. Figure 6-2 shows an example outbound
 2617 pipeline for email checks.

2618

2619

Figure 6-2 Outbound email "pipeline" for UBE filtering

2620 6.3.1 Approved/Non-approved Sender Lists

2621 The most basic technique to reduce UBE is to simply accept or deny messages based on some list
 2622 of known bad or known trusted senders. This is often the first line of UBE defense utilized by an
 2623 enterprise because, if a message was received from a known bad sender, it could reasonably be
 2624 dropped without spending resources in further processing. Or, email originating from a trusted
 2625 source could be marked so as not to be subject to other anti-UBE checks and inadvertently
 2626 deleted or thrown out.

2627 A *non-approved sender list* can be composed of individual IP addresses, IP blocks, or sending
 2628 domain bases [RFC5782]. For example, it is normal for enterprises to refuse email from senders
 2629 using a source address that has not been allocated, or part of a block reserved for private use (such
 2630 as 192.168/16). Or an administrator could choose to not accept email from a given domain if
 2631 there is no reason to assume that they have any interaction with senders using a given domain.
 2632 This could be the case where an organization does not do business with certain countries and may
 2633 refuse mail from senders using those country code Top Level Domains (ccTLDs).

2634 Given the changing nature of malicious UBE, static lists are not effective. Instead, a variety of
 2635 third party services produce dynamic lists of known bad UBE senders that enterprise
 2636 administrators can subscribe to and use. These lists are typically accessed by DNS queries and
 2637 include the non-commercial ventures such as the Spamhaus Project²⁹ and the Spam and Open

²⁹ <https://www.spamhaus.org/>

2638 Relay Blocking System (SORBS)³⁰, as well as commercial vendors such as SpamCop.³¹ An
2639 extensive list of DNS-based blacklists can be found at <http://www.dnsbl.info>. Because an
2640 individual service may be unavailable, many organizations configure their mailers to use
2641 multiple blacklists. Email administrators should use these services to maintain a dynamic reject
2642 list rather than attempting to maintain a static list for a single organization.

2643 An *approved list* is the opposite of a non-approved list. Instead of refusing email from a list of
2644 known bad actors, an approved list is composed of known trusted senders. It is often a list of
2645 business partners, community members, or similar trusted senders that have an existing
2646 relationship with the organization or members of the organization. This does not mean that all
2647 email sent by members on an approved list should be accepted without further checks. Email sent
2648 by an approved sender may not be subject to other anti-UBE checks but may still be checked for
2649 possible malware or malicious links. Email administrators wishing to use approved list should be
2650 very stringent about which senders make the list. Frequent reviews of the list should also occur
2651 to remove senders when the relationship ends, or add new members when new relationships are
2652 formed. Some email tools allow for end users to create their own approved list, so administrators
2653 should make sure that end users does not approve a known bad sender.

2654 A list of approved/non-approved receivers can also be constructed for outgoing email to identify
2655 possible victims of malicious UBE messages or infected hosts sending UBE as part of a botnet.
2656 That is, a host or end user sending email to a domain, or setting the message-From: address
2657 domain to one listed in a non-approved receiver list. Again, since this is a relatively easy
2658 (computational) activity, it should be done before any more intensive scanning tools are used.

2659 **6.3.2 Domain-based Authentication Techniques**

2660 Techniques that use sending policy encoded in the DNS, such as Sender Policy Framework
2661 (SPF), DomainKeys Identified Mail (DKIM), and Domain-based Message Authentication and
2662 Reporting Conformance (DMARC) can also be used to reduce some UBE. Receiving MTAs use
2663 these protocols to see if a message was sent by an authorized sending MTA for the purported
2664 domain. These protocols are discussed in Section 4 and should be utilized by email
2665 administrators for both sending and receiving email.

2666 These protocols only authenticate that an email was sent by a mail server that is considered a
2667 valid email sender by the purported domain and does not authenticated the contents of the email
2668 message. Messages that pass these checks should not automatically be assumed to not be UBE,
2669 as a malicious bulk email sender can easily set up and use their own sending infrastructure that
2670 would pass these checks. Likewise, malicious code that uses an end user's legitimate account to
2671 send email will also pass domain-based authentication checks.

2672 Domain-based authentication checks require more processing by the receiver MTA and thus
2673 should be performed on any mail that has passed the first set of blacklist checks. These checks do
2674 not require the MTA to have the full message and can be done before any further and more

³⁰ <http://www.sorbs.net/>

³¹ <https://www.spamcop.net/>

2675 computationally expensive content checks.³²

2676 **6.3.3 Content Filtering**

2677 The third type of UBE filtering measures involves analysis of the actual contents of an email
2678 message. These filtering techniques examine the content of a mail message for words, phrases or
2679 other elements (images, web links, etc.) that indicate that the message may be UBE.

2680 Examining the textual content of an email message is done using word/phrase filters or Bayesian
2681 filters [UBE1] to identify possible UBE. Since these techniques are not foolproof, most tools that
2682 use these techniques allow for administrators or end users to set the threshold for UBE
2683 identification or allow messages to be marked as possible UBE to prevent false positives and the
2684 deletion of valid transactional messages.

2685 Messages that contain URLs or other non-text elements (or attachments) can also be filtered and
2686 tested for possible malware, UBE advertisements, etc. This could be done via blacklisting
2687 (blocking email containing links to known malicious sites) or by opening the links in a
2688 sandboxed browser-like component³³ in an automated fashion to record the results. If the activity
2689 corresponds to anomalous or known malicious activity, the message will be tagged as malicious
2690 UBE and deleted before placed into the end-user's in-box.

2691 Content filtering and URL analysis is more computationally expensive than other UBE filtering
2692 techniques since the checks are done over the message contents. This means that the checks are
2693 often done after blacklisting and domain-based authentication checks have completed. This
2694 avoids accepting and processing email from a known bad or malicious sender.

2695 Content filtering could also be applied to outgoing email to identify possible botnet infection or
2696 malicious code attempting to use systems within the enterprise to send UBE. Some content filters
2697 may include organization-specific filters or keywords to prevent the loss of private or
2698 confidential information.

2699 **6.4 User Education**

2700 The final line of defense against malicious UBE is an educated end user. An email user that is
2701 aware of the risks inherent in using email should be less likely to fall victim to fraud attempts,
2702 social engineering or convinced into clicking links containing malware. While such training may
2703 not stop all suspicious email, often times an educated end user can sometimes detect and avoid
2704 malicious UBE that passes all automated checks.

2705 How to setup a training regime that includes end user education on the risks of UBE to the
2706 enterprise is beyond the scope of this document. There are several federal programs to help in
2707 end user IT security training, such as the "Stop. Think. Connect."³⁴ program from the
2708 Department of Homeland Security (DHS). Individual organizations should tailor available IT

³² Messages are transmitted incrementally with SMTP, header by header and then body contents and attachments. This allows for incremental and 'just-in-time' header and content filtering.

³³ Sometimes called a "detonation chamber"

³⁴ <http://www.dhs.gov/stopthinkconnect>

2709 security education programs to the needs of their organization.

2710 User education does not fit into the pipeline model in Section 6.3 above, as it takes place at the
2711 time that the end user views the email using their MUA. At this point, all of the above techniques
2712 have failed to identify the threat that now has been placed in the end user's in-box. For outgoing
2713 UBE, the threat is being sent out (possibly using the user's email account) via malicious code
2714 installed on the end user's system. User education can help to prevent users from allowing their
2715 machines to become infected with malicious code, or teach them to identify and remediate the
2716 issue when it arises.

2717 **7 End User Email Security**

2718 **7.1 Introduction**

2719 In terms of the canonical email processing architecture as described in Section 2, the client may
2720 play the role of the MUA. This section we will discuss clients and their interactions and
2721 constraints when using POP3, IMAP, and SMTP. The range of an end user's interactions with a
2722 mailbox is usually done using one of two classes of clients: webmail clients and standalone
2723 clients. These clients communicate with the mailbox in different ways. Webmail clients use
2724 HTTPS. These are discussed in Section 7.2. Mail client applications for desktop or mobile
2725 devices may use IMAP or POP3 for receiving and SMTP for sending, and these are examined in
2726 Section 7.3. There is also the case of command-line clients, the original email clients that are still
2727 used for certain embedded system accesses. However, these represent no significant proportion
2728 of the enterprise market and will not be discussed in this document.

2729 **7.2 Webmail Clients**

2730 Many enterprises permit email access while away from the workplace or the corporate LAN. The
2731 mechanisms for this access is a Virtual Private Network (VPN) or a web interface through a
2732 browser. In the latter case, the security posture is determined at the web server. Actual
2733 communication between a client and server is conducted over HTTP or HTTPS. Federal agencies
2734 implementing a web-based solution should refer to NIST SP 800-95 [SP800-95] and adhere to
2735 other federal policies regarding web-based services. Federal agencies are required to provide a
2736 certificate that can be authenticated through PKIX to a well-known trust-anchor. An enterprise
2737 may choose to retain control of its own trusted roots. In this case, DANE can be used to
2738 configure a TLSA record and authenticate the certificate using the DNS (see Section 5.2.5).

2739 **7.3 Standalone Clients**

2740 For the purposes of this guide, a *standalone client* refers to a software component used by an end
2741 user to send and/or receive email. Examples of such clients include Mozilla Thunderbird and
2742 Microsoft Outlook. These components are typically found on a host computer, laptop or mobile
2743 device. These components may have many features beyond basic email processing, but these are
2744 beyond the scope of this document.

2745 Sending requires connecting to an MSA or an MTA using SMTP. This is discussed in Section
2746 7.3.2. Receiving is typically done via POP3 and IMAP,³⁵ and mailbox management differs in
2747 each case.

2748 **7.3.1 Sending via SMTP**

2749 Email message submission occurs between a client and a server using the Simple Mail Transfer
2750 Protocol (SMTP) [RFC5321], either using port 25 or 993. The client is operated by an end-user,
2751 and the server is hosted by a public or corporate mail service. Clients should authenticate using

³⁵ Other protocols (MAPI/RPC or proprietary protocols will not be discussed.

2752 client authentication schemes such as usernames and passwords or PKI-based authentication as
2753 provided by the protocol.

2754 It is further recommended that the connection between the client and MSA be secured using TLS
2755 [RFC5246], associated with the full range of protective measures described in Section 5.2.

2756 **7.3.2 Require TLS: Client side TLS Enforcement**

2757 After an MUA submits a message to an MSA for delivery, it cannot guarantee the message
2758 confidentiality (unless it is encrypted end-to-end, see Section 5.3). TLS is negotiated and used
2759 hop by hop, so intermediate MTAs may not offer TLS, and sending MTAs may not wish to use
2760 TLS to submit mail. There is a chance that one MTA-to-MTA hop does not use TLS for
2761 message transfer and thus vulnerable to passive monitoring.

2762 There is work in progress in the IETF to add a new header to email to signal to the sending MTA
2763 that the original sender requests TLS be used for all mail transmissions³⁶. An MUA sets the
2764 option when submitting the mail message to the MSA. The MSA then must establish a TLS
2765 secured channel to the next hop MTA before sending the message to its next destination. This
2766 continues from MTA to MTA until the final delivery of the message. If a TLS connection cannot
2767 be established, the sender must return an error message to the original sender.

2768 **7.3.3 Receiving via IMAP**

2769 Email message receiving and management occurs between a client and a server using the Internet
2770 Message Access Protocol (IMAP) protocol [RFC3501] over port 143. A client may be located
2771 anywhere on the Internet, establish a transport connection with the server, authenticate itself, and
2772 manipulate the remote mailbox with a variety of commands. Depending on the server
2773 implementation, it is feasible to have access to the same mailbox from multiple clients. IMAP
2774 has operations for creating, deleting and renaming mailboxes; checking for new messages;
2775 permanently removing messages; parsing; searching; and selective fetching of message
2776 attributes, texts and parts thereof. It is equivalent to the local control of a mailbox and its folders.

2777 Establishing a connection with the server over TCP and authenticating to a mailbox with a
2778 username and password sent without encryption is not recommended. IMAP clients should
2779 connect to servers using TLS [RFC5246], which should be associated with the full range of
2780 applicable protective measures described in Section 5.2.

2781 **7.3.4 Receiving via POP3**

2782 Before IMAP [RFC3501] was invented, the Post Office Protocol (POP3) had been created as a
2783 mechanism for remote users to connect to mailbox, download mail, and delete it off the server. It
2784 was expected at the time that access be from a single, dedicated user, with no conflicts. Provision
2785 for encrypted transport was not made.

2786 The protocol went through an evolutionary cycle of upgrades, and the current instance, POP3

³⁶ J. Fenton "SMTP Require TLS Option" Work in Progress <https://datatracker.ietf.org/doc/draft-ietf-uta-smtp-require-tls/>

2787 [RFC5034] is aligned with the Simple Authentication Security Layer (SASL) [RFC4422] and
 2788 optionally operated over a secure encrypted transport layer, TLS [RFC5246]. POP3 defines a
 2789 simpler mailbox access alternative to IMAP, without the same fine control over mailbox file
 2790 structure and manipulation mechanisms. Users who access their mailboxes from multiple hosts
 2791 or devices should use IMAP clients instead of POP3, to maintain a synchronization of clients
 2792 with the single, central mailbox.

2793 Clients with POP3 access should configure them to connect over TLS, which should be
 2794 associated with the full range of protective measures described above in Section 5.2, Email
 2795 Transmission Security.

2796 **Security Recommendation 7-1:** IMAP and POP3 clients should connect to servers using
 2797 TLS [RFC5246] and be associated with the full range of protective measures described in
 2798 Section 5.2, Email Transmission Security. Connecting with unencrypted TCP and authenticating
 2799 with username and password is strongly discouraged.

2800 7.4 Mailbox Security

2801 The security of data in transit is only useful if the security of data at rest can be assured. This
 2802 means maintaining confidentiality at the sender and receiver endpoints of:

- 2803 • The user's information (e.g. mailbox contents), and
- 2804 • Private keys.

2805 Confidentiality and the encryption for data in transit is discussed in Section 7.4.1, while the
 2806 confidentiality of data at rest is discussed in Section 7.4.2.

2807 7.4.1 Confidentiality of Data in Transit

2808 A common element for users of TLS for SMTP, IMAP and POP3, as well as for S/MIME and
 2809 OpenPGP, is the need to maintain current and accessible private keys, as used for decryption of
 2810 received mail, and signing of authenticated mail. A range of different users require access to
 2811 these disparate private keys:

- 2812 • The email server must have use of the private key used for TLS and the private key must
 2813 be protected.
- 2814 • The end user (and possibly an enterprise security administrator) must have access to
 2815 private keys for S/MIME or OpenPGP message signing and key decipherment.

2816 Special care is needed to ensure that only the relevant parties have access and control over the
 2817 respective keys. For federal agencies, this means compliance with all relevant policy and best
 2818 practice for the protection of key material [SP800-57pt1].

2819 **Security Consideration 7-2:** Enterprises should establish a cryptographic key management
 2820 system (CKMS) for keys associated with protecting email sessions with end users. For federal
 2821 agencies, this means compliance with all relevant policy and best practice for the protection of
 2822 key material [SP800-57pt1].

2823 7.4.2 Confidentiality of Data at Rest

2824 This publication is about securing email and its associated data. This is one aspect of securing
2825 data in transit. To the extent that email comes to rest in persistent storage in mailboxes and file
2826 stores, there is some overlap with NIST SP 800-111 [SP800-111].

2827 There is an issue in the tradeoff between accessibility and confidentiality when using mailboxes
2828 as persistent storage. End users and their organizations are expected to manage their own private
2829 keys, and historical versions of these may remain available to enable the decryption of mail
2830 encrypted by communicating partners, and to authenticate (and decrypt) cc: mail sent to partners,
2831 which have been also stored locally. Partners who sign their mail, and decrypt received mail,
2832 make their public keys available through certificates, or through DANE records (i.e., TLSA,
2833 OPENPGPKEY, SMIMEA) in the DNS. These certificates generally have a listed expiry date
2834 and are rolled over and replaced with new certificates containing new keys. Such partners' mail
2835 stored persistently in a mailbox beyond the key expiry and rollover date may cease to be readable
2836 if the mailbox owner does not maintain a historical inventory of partners' keys and certificates.
2837 For people who use their mailboxes as persistent, large-scale storage, this can create a
2838 management problem. If keys cannot be found, historical encrypted messages cannot be read.

2839 Email keys for S/MIME and OpenPGP should only be used for messages in transit. Messages
2840 intended for persistent local storage should be decrypted, stored in user-controllable file storage,
2841 and, if necessary, re-encrypted with user-controlled keys. For maximum security, all email
2842 should be stored encrypted—for example, with a cryptographic file system.

2843 **Security Recommendation 7-3:** Cryptographic keys used for encrypting data in persistent
2844 storage (e.g., in mailboxes) should be different from keys used for the transmission of email
2845 messages.

2846 7.5 Security Recommendation Summary

2847 **Security Recommendation 7-1:** IMAP and POP3 clients should connect to servers using
2848 TLS [RFC5246] and be associated with the full range of protective measures described in
2849 Section 5.2, Email Transmission Security. Connecting with unencrypted TCP and authenticating
2850 with username and password is strongly discouraged.

2851 **Security Consideration 7-2:** Enterprises should establish a cryptographic key management
2852 system (CKMS) for keys associated with protecting email sessions with end users. For federal
2853 agencies, this means compliance with all relevant policy and best practice for the protection of
2854 key material [SP800-57pt1].

2855 **Security Recommendation 7-3:** Cryptographic keys used for encrypting data in persistent
2856 storage (e.g., in mailboxes) should be different from keys used for the transmission of email
2857 messages.

2858

2859 **Appendix A—Acronyms**

2860 Selected acronyms and abbreviations used in this paper are defined below.

DHS	Department of Homeland Security
DKIM	DomainKeys Identified Mail
DMARC	Domain-based Message Authentication, Reporting and Conformance
DNS	Domain Name System
DNSSEC	Domain Name System Security Extensions
FISMA	Federal Information Security Management Act
FRN	Federal Network Resiliency
IMAP	Internet Message Access Protocol
MDA	Mail Delivery Agent
MSA	Mail Submission Agent
MTA	Mail Transport Agent
MUA	Mail User Agent
MIME	Multipurpose Internet Message Extensions
NIST SP	NIST Special Publication
PGP/OpenPGP	Pretty Good Privacy
PKI	Public Key Infrastructure
POP3	Post Office Protocol, Version 3
RR	Resource Record
S/MIME	Secure/Multipurpose Internet Mail Extensions
SMTP	Simple Mail Transport Protocol
SPF	Sender Policy Framework
TLS	Transport Layer Security
VM	Virtual Machine
VPN	Virtual Private Network

2876

2877 **Appendix C—Overlay of NIST SP 800-53 Controls to Email Messaging Systems**

2878 **C.1 Introduction**

2879 The following is an overlay of the NIST SP 800-53 Rev. 5 controls and gives detail on how
2880 email systems can comply with the applicable controls. This overlay follows the process
2881 documented in SP 800-53r5 Appendix G [SP800-53]. Here, “email system” is taken to mean any
2882 system (as defined by FIPS 199), that is said to generate, send, or store email messages for an
2883 enterprise. This section attempts to identify individual controls (or control families) that are
2884 relevant to email systems, and to select specific guidance that should be used to comply with
2885 each control.

2886 This section does not introduce new controls that do not exist in SP 800-53 Rev. 5 and does not
2887 declare any control unnecessary for a given system and control baseline. This section only lists
2888 controls that directly relate to deploying and operating a trustworthy email service. Further
2889 guidance is given for each control to assist administrators in meeting compliance requirements.

2890 **C.2 Applicability**

2891 The purpose of this overlay is to provide guidance for securing the various email systems used
2892 within an enterprise. This overlay has been prepared for use by federal agencies. It may be used
2893 by nongovernmental organizations on a voluntary basis.

2894 **C.3 Trustworthy Email Overlay**

2895 The overlay breaks down NIST SP 800-53 Rev. 5 controls according to specific email security
2896 protocols: Domain-based authentication (i.e., SPF, DKIM, DMARC, etc.), SMTP over TLS and
2897 end-to-end email security (i.e., S/MIME or OpenPGP). To avoid confusion as to which control
2898 applies to which technology, these controls are only listed once, with a justification included to
2899 provide more email-specific guidance as to why and how the control should apply to an email
2900 system.

2901 Just because a control is not explicitly listed below does not mean that the control (or control
2902 family) is not applicable to an email system. Controls (or control families) that apply to all
2903 systems for a given baseline would still apply. For example, the **IA-7 CRYPTOGRAPHIC**
2904 **MODULE AUTHENTICATION** control could be said to apply to all systems that perform
2905 some cryptographic function for a given baseline, but administrators should already be aware of
2906 this general control, and no additional special consideration is needed just for email systems. The
2907 controls below should be seen as additional controls that should be applied for a give control
2908 baseline. A general control family may be listed below to alert administrators that there could be
2909 implications of the control family that impact email operations, so administrators should consider
2910 how the email service should address the family as applicable.

2911 The trustworthy email service-relevant controls are listed below. The control body and relevant
2912 accompanying information is included to assist the reader, but the entire control is not included.
2913 Readers are encouraged to consult NIST SP 800-53 Rev. 5 for the full text and all accompanying
2914 material. In addition, a justification is included for each control (or control family) to state why
2915 the control is included, how it applies to email, and to provide guidance from NIST SP 800-177

2916 (or another document) to comply with the control.

2917

2918 **C.4 Control Baselines**

2919 The table below is taken from NIST SP 800-53 Rev. 5 Appendix D. It lists the control baselines
 2920 for the three risk levels: Low, Moderate and High. To this is added the new control
 2921 recommendations and extensions for the email system overlay. Additional requirements and
 2922 control extensions are listed **in bold**. Justification of the additions are listed below the table.

2923

Table C-1: Overlay Control Baselines

		CONTROL BASELINES		
		LOW	MODERATE	HIGH
CONTROL Number	Control Name			
Access Control (AC)				
AC-1	ACCESS CONTROL POLICY AND PROCEDURES	AC-1	AC-1	AC-1
AC-2	ACCOUNT MANAGEMENT	AC-2	AC-2 (1,2,3,4,10,13)	AC-2 (1,2,3,4,5,10,11,12,13)
AC-3	ACCESS ENFORCEMENT	AC-3	AC-3	AC-3
AC-4	INFORMATION FLOW ENFORCEMENT	-	AC-4	AC-4(4)
AC-5	SEPARATION OF DUTIES	-	AC-5	AC-5
AC-6	LEAST PRIVILEGE	AC-6 (6,7,9)	AC-6 (1,2,5,7,9,10)	AC-6 (1,2,3,5,7,9,10)
AC-7	UNSUCCESSFUL LOGON ATTEMPTS	AC-7	AC-7	AC-7
AC-8	SYSTEM USE NOTIFICATION	AC-8	AC-8	AC-8
AC-9	PREVIOUS LOGON (ACCESS) NOTIFICATION	-	-	-

AC-10	CONCURRENT SESSION CONTROL	-	-	AC-10
AC-11	DEVICE LOCK	-	AC-11(1)	AC-11(1)
AC-12	SESSION TERMINATION	-	AC-12	AC-12
AC-14	PERMITTED ACTIONS WITHOUT IDENTIFICATION OR AUTHENTICATION	AC-14	AC-14	AC-14
AC-16	SECURITY AND PRIVACY ATTRIBUTES	-	-	-
AC-17	REMOTE ACCESS	AC-17	AC-17(1,2,3,4)	AC-17(1,2,3,4)
AC-18	WIRELESS ACCESS	AC-18	AC-18 (1)	AC-18 (1,3,4,5)
AC-19	ACCESS CONTROL FOR MOBILE DEVICES	AC-19	AC-19 (5)	AC-19 (5)
AC-20	USE OF EXTERNAL SYSTEMS	AC-20	AC-20 (1,2)	AC-20 (1,2)
AC-21	INFORMATION SHARING	AC-21	AC-21	AC-21
AC-22	PUBLICALLY ACCESSIBLE CONTENT	AC-22	AC-22	AC-22
AC-23	DATA MINING PROTECTION	-	-	-
AC-24	ACCESS CONTROL DECISIONS	-	-	-
AC-25	REFERENCE MONITOR	-	-	-
Awareness and Training (AT)				
AT-1	AWARENESS AND TRAINING POLICY AND PROCEDURES	AT-1	AT-1	AT-1

2924

2925 **C.5 Additional/Expanded Controls**

2926 **AC-21 INFORMATION SHARING**

2927 **Control:**

- 2928 a. Facilitate information sharing by enabling authorized users to determine whether access
- 2929 authorizations assigned to the sharing partner match the access restrictions and privacy
- 2930 authorizations on the information for [*Assignment: organization-defined information*
- 2931 *sharing circumstances where user discretion is required*]; and
- 2932 b. Employ [*Assignment: organization-defined automated mechanisms or manual processes*]
- 2933 to assist users in making information sharing and collaboration decisions.

2934

2935 **Justification:** If an enterprise has deployed DMARC and is collecting forensic reports (see
 2936 Section 4.6.5), administrators should make sure that any private data that may be contained in the

2937 report is redacted and not divulged to unauthorized parties.

2938 **Baseline:** All levels

2939

2940 **AT-2 AWARENESS TRAINING**

2941 Control: Provide basic security and privacy awareness training to system users (including
2942 managers, senior executives, and contractors):

2943 a. As part of initial training for new users;

2944 b. When required by system changes; and

2945 c. [*Assignment: organization-defined frequency*] thereafter.

2946 Control Enhancements:

2947 **(1) AWARENESS TRAINING | PRACTICAL EXERCISES**

2948 **Include practical exercises in awareness training that simulate security and privacy**
2949 **incidents.**

2950 Supplemental Guidance: Practical exercises may include, for example, no-notice
2951 social engineering attempts to collect information, gain unauthorized access, or
2952 simulate the adverse impact of opening malicious email attachments or invoking,
2953 via spear phishing attacks, malicious web links. Privacy-related practical exercises
2954 may include, for example, practice modules with quizzes on handling personally
2955 identifiable information and affected individuals in various scenarios.

2956 **Justification:** Administrators should have training on how to use DMARC reporting to
2957 identify and react to email borne attacks. See Section 4.6. All users of an email system
2958 should have training on how to identify and take action to stop phishing attempts,
2959 opening malicious attachments and social engineering attacks using email. This could
2960 include looking for and noting the presence of digital signatures (S/MIME or OpenPGP),
2961 (see Section 5.3).

2962 **Baseline:** AT-2 (1) All levels

2963

2964 **AU-10 NON-REPUDIATION**

2965 Control: Protect against an individual (or process acting on behalf of an individual) falsely

2966 denying having performed [*Assignment: organization-defined actions to be covered by*
2967 *non-repudiation*].

2968 Control Enhancements:

2969 **(1) NON-REPUDIATION | ASSOCIATION OF IDENTITIES**

2970 **(a). Bind the identity of the information producer with the information to [*Assignment:***
2971 ***organization-defined strength of binding*]; and**

2972 **(b). Provide the means for authorized individuals to determine the identity of the**
2973 **producer of the information.**
2974

2975 Supplemental Guidance:

2976 This control enhancement supports audit requirements that provide organizational
2977 personnel with the means to identify who produced specific information in the event of
2978 an information transfer. Organizations determine and approve the strength of the binding
2979 between the information producer and the information based on the security category of
2980 the information and relevant risk factors.

2981 **Justification:** Organizations using email for information transfer should use S/MIME or
2982 OpenPGP to provide authentication of the original sender (via a digital signature). In addition,
2983 the organization should provide an alternate means to publish sender digital signature certificates
2984 so that receivers can validate email digital signatures. See Section 5.3.

2985 **Baseline:** AU-10 (1) HIGH only

2986

2987 **IA-9 SERVICE IDENTIFICATION AND AUTHENTICATION**

2988 **Control:** Identify and authenticate [*Assignment: organization-defined system services and*
2989 *applications*] before establishing communications with devices, users, or other services or
2990 applications.

2991 Control Enhancements:

2992 **(1) SERVICE IDENTIFICATION AND AUTHENTICATION | INFORMATION EXCHANGE**

2993 **Ensure that service providers receive, validate, and transmit identification and**
2994 **authentication information.**

2995 **Justification:** An organization should have certificates to authenticate MTAs that receive mail from
2996 external sources (i.e. the Internet) and for MTAs that host users' inboxes that are accessed via
2997 POP3, IMAP or Microsoft Exchange. See Section 2.3.

2998 Control Extension:

2999 (2) The organization should provide additional methods to validate a given MTA's certificate.
3000 Examples of this include DANE TLSA RRs (see Section 5.2.4) or SMTP Strict Transport
3001 Security (work-in-progress).

3002 **Baseline:** MOD: IA-9(1), HIGH: IA-9(1)(2)

3003

3004 **IP-X INDIVIDUAL PARTICIPATION** (potential of entire family)

3005 **Justification:** Organizations that use incoming and/or outgoing email content scanning should
3006 have a policy and set of procedures in place to make users aware of the organization's email
3007 policy. This scanning could be done for a variety of reasons (see Section 6.3.3). This includes
3008 consent, privacy notice and the remediation taken when the violations of the policy are detected.

3009

3010 **IR-X INCIDENT RESPONSE** (potential of entire family)

3011 Justification: Organizations deploying DMARC (see Section 4.6) may need to generate a new
3012 plan to handle DMARC forensic reports that indicate their domain is being spoofed as part of a
3013 phishing campaign against a third party. This is not necessarily an attack against the
3014 organization, but an attack using the organization's reputation to subvert one or more victims.
3015 DMARC forensic reports can be used to identify these attacks that may have been unknown to
3016 the organization previously.

3017

3018 **PS-4 PERSONNEL TERMINATION**

3019 Control: Upon termination of individual employment:

3020 a. Disable system access within [*Assignment: organization-defined time-period*];

3021 b. Terminate or revoke any authenticators and credentials associated with the
3022 individual;

3023 c. Conduct exit interviews that include a discussion of [*Assignment: organization-*
3024 *defined information security topics*];

3025 d. Retrieve all security-related organizational system-related property;

3026 e. Retain access to organizational information and systems formerly controlled by

3027 terminated individual; and

3028 f. Notify [*Assignment: organization-defined personnel or roles*] within [*Assignment:*
3029 *organization-defined time-period*].

3030 **Justification:** This control is selected so that when an email administrator leaves a position, all
3031 credentials that the administrator had access to are revoked. This includes key pairs used to with
3032 SMTP over TLS (see Section 5.2), DKIM (see Section 4.5) and/or S/MIME key pairs.

3033 In addition, when an organization terminates a third-party email service, administrators should
3034 revoke any credentials that the third party may have had for the organizations. Examples of this
3035 include DKIM keys used by third party senders stored in the organization's DNS (see Section
3036 4.5.11) and SPF entries used to authenticate third-party senders (see Section 4.4.4).

3037 **Baseline:** All Levels

3038

3039 **PS-6 ACCESS AGREEMENTS**

3040 Control:

3041 a) Develop and document access agreements for organizational systems;

3042 b) Review and update the access agreements [*Assignment: organization-defined*
3043 *frequency*]; and

3044 c) Verify that individuals requiring access to organizational information and systems:

3045 1. Sign appropriate access agreements prior to being granted access; and

3046 2. Re-sign access agreements to maintain access to organizational systems
3047 when access agreements have been updated or [*Assignment:*
3048 *organization-defined frequency*].

3049 **Justification:** See PS-5 above.

3050 **Baseline:** All levels.

3051

3052 **SC-7 BOUNDARY PROTECTION**

3053 Control:

- 3054 a) Monitor and control communications at the external boundary of the system and at
3055 key internal boundaries within the system;
- 3056 b) Implement subnetworks for publicly accessible system components that are
3057 [*Selection: physically; logically*] separated from internal organizational networks;
3058 and
- 3059 c) Connect to external networks or systems only through managed interfaces
3060 consisting of boundary protection devices arranged in accordance with an
3061 organizational security and privacy architecture.

3062 Control Extensions:

3063 **(10) BOUNDARY PROTECTION | PREVENT UNAUTHORIZED EXFILTRATION**

3064 **(a) Prevent the unauthorized exfiltration of information; and**

3065 **(b) Conduct exfiltration tests [*Assignment: organization-defined frequency*].**

3066 Supplemental Guidance: This control enhancement applies to intentional and
3067 unintentional exfiltration of information. Safeguards to prevent unauthorized
3068 exfiltration of information from systems may be implemented at internal
3069 endpoints, external boundaries, and across managed interfaces and include, for
3070 example, strict adherence to protocol formats; monitoring for beaconing activity
3071 from systems; monitoring for steganography; disconnecting external network
3072 interfaces except when explicitly needed; disassembling and reassembling packet
3073 headers; employing traffic profile analysis to detect deviations from the volume
3074 and types of traffic expected within organizations or call backs to command and
3075 control centers; and implementing data loss and data leakage prevention tools.
3076 Devices that enforce strict adherence to protocol formats include, for example,
3077 deep packet inspection firewalls and XML gateways. These devices verify
3078 adherence to protocol formats and specifications at the application layer and
3079 identify vulnerabilities that cannot be detected by devices operating at the network
3080 or transport layers. This control enhancement is analogous with data loss/data
3081 leakage prevention and is closely associated with cross-domain solutions and
3082 system guards enforcing information flow requirements.

3083 **(11) BOUNDARY PROTECTION | RESTRICT INCOMING COMMUNICATIONS TRAFFIC**

3084 **Only allow incoming communications from [*Assignment: organization-defined***
3085 ***authorized sources*] to be routed to [*Assignment: organization-defined authorized***

3086 ***destinations***].

3087 Supplemental Guidance: This control enhancement provides determinations that
 3088 source and destination address pairs represent authorized/allowed
 3089 communications. Such determinations can be based on several factors including,
 3090 for example, the presence of such address pairs in the lists of authorized/allowed
 3091 communications; the absence of such address pairs in lists of
 3092 unauthorized/disallowed pairs; or meeting more general rules for
 3093 authorized/allowed source and destination pairs.

3094 **Justification**: Email systems should have incoming mail filters to detect, quarantine or reject
 3095 mail from known bad senders (e.g., known Spam or malicious senders). Email systems should
 3096 also implement outgoing mail filters to prevent sensitive data exfiltration and detect internal
 3097 hosts that may be compromised to send Spam using the organization's reputation to spoof
 3098 victims.

3099 **Baseline**: MOD: SC-7 (10), HIGH: SC-7 (10) (11)

3100

3101 **SC-8 TRANSMISSION CONFIDENTIALITY AND INTEGRITY**

3102 Control: Protect the [*Selection (one or more): confidentiality; integrity*] of transmitted
 3103 information.

3104 Control Enhancements:

3105 **(1)** TRANSMISSION CONFIDENTIALITY AND INTEGRITY | CRYPTOGRAPHIC PROTECTION

3106 **Implement cryptographic mechanisms to [*Selection (one or more): prevent***
 3107 ***unauthorized disclosure of information; detect changes to information*]** during
 3108 **transmission.**

3110 Supplemental Guidance: Encrypting information for transmission protects information
 3111 from unauthorized disclosure and modification. Cryptographic mechanisms
 3112 implemented to protect information integrity include, for example, cryptographic
 3113 hash functions which have common application in digital signatures, checksums,
 3114 and message authentication codes.
 3115

3116 **Justification**: Email systems should deploy security protocols to protect the integrity of email
 3117 messages and the confidentiality of messages in transit. For integrity protection, email systems
 3118 should use DKIM (see Section 4.5) and/or S/MIME digital signatures (see Section 5.3) when
 3119 sending messages. For confidentiality, email systems should use SMTP over TLS (see Section
 3120 5.2).

3121 **Baseline:** MOD: SC-8 (1), HIGH: SC-8 (1)

3122

3123 **SC-23 SESSION AUTHENTICITY**

3124 **Control:** Protect the authenticity of communications sessions.

3125 **Supplemental Guidance:** This control addresses communications protection at the session,
3126 versus packet level. Such protection establishes grounds for confidence at both ends of
3127 communications sessions in the ongoing identities of other parties and in the validity of
3128 information transmitted. Authenticity protection includes, for example, protecting against
3129 man-in-the-middle attacks and session hijacking, and the insertion of false information
3130 into sessions.

3131 **Control Enhancements:**

3132 **(5) SESSION AUTHENTICITY | ALLOWED CERTIFICATE AUTHORITIES**

3133 **Only allow the use of [Assignment: organization-defined certificate authorities] for**
3134 **verification of the establishment of protected sessions.**

3135 **Supplemental Guidance:** Reliance on certificate authorities (CAs) for the establishment of
3136 secure sessions includes, for example, the use of Transport Layer Security (TLS)
3137 certificates. These certificates, after verification by their respective CAs, facilitate the
3138 establishment of protected sessions between web clients and web servers.

3139 **Justification:** Prior to establishing a TLS connection for SMTP transmission of email, a sending
3140 MTA should authenticate the certificate provided by the receiving MTA. This authentication
3141 could be PKIX, or an alternative method (e.g. DANE, SMTP-STS, etc.). See Section 5.2 for
3142 details.

3143 **Baseline:** MOD: SC-23, HIGH: SC-23(5)

3144

3145 **SC-44 DETONATION CHAMBERS**

3146 **Control:** Employ a detonation chamber capability within [Assignment: organization-
3147 defined system, system component, or location].

3148 **Supplemental Guidance:** Detonation chambers, also known as dynamic execution

3149 environments, allow organizations to open email attachments, execute untrusted or
3150 suspicious applications, and execute Universal Resource Locator requests in the safety of
3151 an isolated environment or a virtualized sandbox. These protected and isolated execution
3152 environments provide a means of determining whether the associated attachments or
3153 applications contain malicious code. While related to the concept of deception nets, this
3154 control is not intended to maintain a long-term environment in which adversaries can
3155 operate and their actions can be observed. Rather, it is intended to quickly identify
3156 malicious code and reduce the likelihood that the code is propagated to user
3157 environments of operation or prevent such propagation completely.

3158 **Justification:** Incoming email from outside sources should be examined in detonation chambers
3159 to protect against malicious code or URLs contained in the email message. See Section 6.

3160 **Baseline:** All Levels
