# Bond Math 2 The Economics of Bonds Piecing Together Bond Finances -Introduction of Speakers 

Robert G. Friar, Jr.<br>Managing Director, The PFM Group<br>Kenneth D. Fullerton<br>Managing Director, The PFM Group

## The California Debt and Investment Advisory Commission Technical Webinar Series

## Robert G. Friar, Jr. <br> Managing Director, The PFM Group

- Over 27 years of experience in Municipal Finance
-Has been involved in all aspects of the business across the country, as both an underwriter and financial advisor
- Currently assists clients in the structuring and financing of complex airport projects

## Kenneth D. Fullerton <br> Managing Director, The PFM Group

- Over 30 years of experience in Municipal finance
-Has provided financial advice on over 100 financings totaling over $\$ 15$ billion for airport clients.
-Current airport clients include Chicago, New York, Washington, Tampa, San Jose, Dakland, Salt Lake, Reno, Columbus, Providence, Ft. Myers, Pittsburgh, Memphis and many others

Piec ing Together Bond Finance Presented by Kenneth D. Fullerton \& Robert G. Friar, Jr.雪

## Topics

## 1. The Yield Curve

Definition: A curve on a graph in which the yield of fixed-interest securities is plotted against the length of time they have to run to maturity.

Under nomal conditions, interest rates on bonds with shorter maturities are lower tha $n$ bondswith longermaturities.

Normal Yield Curve
(Upwardly Sloping)

Years to Maturity

## The Yield Curve <br> (continued)

There are a number of theories that attempt to explain why ratestend to be higheron longer maturitiesthan on shorter ones (an "upwardly sloping" yield curve). Two of these are:

Liquidity Premium: All things being equal, investorsface greater uncerta inty holding longertem bondsthan shorter term bonds. Many more unpredictable things are likely to happen in the next ten years than in the next two and investors demand higherrates to compensate them forthis risk.

Market Expectations: This theory says that investors, in general, expect interest rates in the future will be higherthan they are today. They therefore demand an interest rate on longer maturities that would give them the same expected total retum had they altematively invested in a shorter maturity and then reinvested at the higher future rate that they are expecting.

## The Yield Curve (continued)

The yield curve can, and does, change overtime as economic conditionschange. It can flatten so that short term rates and long term rates are the same.

## The Yield Curve <br> (continued)

The yield curve can even become inverted where long term rates are lowerthan short tem rates. An inverted yield curve isconsidered to be a negative economic indicator. Inversion indicates that investors believe interest rates will be lower in the future and that often means that economic activity is at least likely to slow and may even mean that a recession is coming. A tightening of short term interest rates by the Federal Reserve in order to slow the economy or to reign in inflation can lead to an inverted yield curve. Inverted Yield Curve

## The Yield Curve (continued)

So far in 2011 the US Treasury yield curve has flattened considerably:

## 2. Bond Pricing

## Par, Discount and Premium Bonds

The yield on a bond is a measure of the retum, or eamings, realized by holding the bond. The yield is determined by the market, the overall supply and demand forthe bond. As we saw in the previous section the yield will usually vary depending on the final maturity of the bond.

The price to be paid for a bond also varies based on the coupon that is attached to the bond. The coupon is the actual rate of interest that is paid to the bond investor. A 5\% coupon on a $\$ 100$ bond pays $\$ 5 /$ year.

## ParBond

A parbond is a bond that can be purchased at $100 \%$ of its underlying value. A bond that hasa principal a mount of $\$ 100$ at maturity will sell for $\$ 100$ right now if its coupon is the same as the curent market yield.

Of course, market yieldschange all the time so a bond that is trading at partoday may not be trading at par tomorrow.

## Bond Pricing

## Par, Discount and Premium Bonds

One of the more confusing aspects of bonds is the relationship between price and yield:
If you own a bond and the market yield rises the price of the bond falls.
If you own a bond and the market yield falls the price of the bond rises.

|  | Years to Maturity | Coupon | Market Yield | Price |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| This is a table |  |  |  |  |  |
|  | 5 | 5.00\% | 4.00\% | 104.491 | P |
| that shows |  |  |  |  | R |
|  | 5 | 5.00\% | 4.25\% | 103.347 | E |
| what happens |  |  |  |  | M |
|  | 5 | 5.00\% | 4.50\% | 102.217 | I |
| to the price of a |  |  |  |  | U |
|  | 5 | 5.00\% | 4.75\% | 101.101 | M |
| bond with a 5\% | 5 | 5.00\% | 5.00\% | 100.000 | PAR |
| coupon as market |  |  |  |  | D |
| couponas market | 5 | 5.00\% | 5.25\% | 98.913 | I |
| yields change |  |  |  |  | 5 |
|  | 5 | 5.00\% | 5.50\% | 97.840 | C |
|  | 5 | 5.00\% | 5.75\% | 96.781 | U |
|  |  |  |  |  | N |
|  | 5 | 5.00\% | 6.00\% | 95.735 | T |

## Bond Pricing (continued)

## Discount Bond

If market yields rise to $6 \%$, the bond with a $5 \%$ coupon is now paying a rate that is less valuable in the market. The price of this less valuable bond will therefore fall and it will trade at a discount to par, say $95 \%$ of its original par value if it is five years until the bond matures. By trading at a discount this bond will have an overall yield of $6 \%$ (the rate demanded by the market): $5 \%$ from the coupon and an additional $1 \%$ year from the discount as the price of the bond will slowly a pproach $100 \%$ of its par value at maturity.

One reason an investor might prefer a discount bond: Call protection. In a market environment where interest rates are falling it will take longerfora bond with a lower coupon to be profitably called by the issuer of the bond when compared to a higher coupon bond.

## Bond Pricing (continued)

## Premium Bond

If market yieldsfall to $4 \%$, the bond with a $5 \%$ coupon is now paying a rate the is more valuable in the market. The price of this more valuable bond will therefore rise and it will trade at a premium to par, say $105 \%$ of its original parvalue if it is five years until the bond matures. By trading at a premium this bond will have an overall yield of 4\% (the rate demanded by the market): $5 \%$ from the coupon and $-1 \%$ yearfrom the premium as the price will slowly depreciate to $100 \%$ of its parvalue at maturity.

One reason an investor might prefer a premium bond: Less volatility. If interest rates rise after you purchase the bond the value of the bond will fall...but not asquickly as a lower coupon bond would. This is because more of the value of the bond is in the stream of early coupon payments to be received in the near future rather than the final maturity a mount. The present value of payments to be received earlier (in thiscase, the coupon payments) doesn't change as much as payments received later (like the principal a mount at maturity) for a given change in interest rates.

## 3. OtherTypes of Bonds

Capital Appreciation and Zero Coupon Bonds

- Most fixed rate bonds pay semi-a nnual interest at the same rate over their entire life...the coupon rate on the bond. Thistype of bond is called a "Cument Interest Bond."
> Some bondsdon't pay any interest until maturity. Since they don't have any coupon payments investors buy them at a discount to their parvalue. For instance, in a market where one year bonds yield $5.00 \%$, a bond that matures in one year but has no coupon payments would sell for $95.238 \%$ of its par value. ( $5 \%$ of 95.238 is 4.762 so that the investor will be eaming $5.00 \%$ on the $\$ 95.238$ he or she spendsto buy the bond, getting $\$ 100$ back a year from now).

Bonds that only pay interest at maturity a re called "Capital Appreciation" or "Zero Coupon" bonds. Mathematic ally, they are identical. The difference is that the initial purchase price is considered to be the principal amount fora Capital Appreciation Bond (or "CAB") while the value at maturity is considered to be the principalamount for Zero Coupon Bond. In either case the value of the bond inc reases over time until maturity.

## OtherTypes of Bonds

## Capital Appreciation and Zero Coupon Bonds

The table below showstwo different debt service payment streams fora $\$ 10$ million bond issued with a $5 \%$ yield. The first is issued as a current interest bond at par (so the coupon is $5.00 \%$ ), the second as a zero coupon bond or CAB.

Debt Service Payments on a ...

| Year | Current Interest Bond |  |  | Zero Coupon Bond or CAB | Accreted Value of Zero Coupon Bond or CAB |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Principal | Interest | Total |  |  |
| 0 |  |  |  |  | 10,000,000 |
| 1 |  | 500,000 | 500,000 |  | 10,500,000 |
| 2 |  | 500,000 | 500,000 |  | 11,025,000 |
| 3 |  | 500,000 | 500,000 |  | 11,576,250 |
| 4 |  | 500,000 | 500,000 |  | 12,155,063 |
| 5 |  | 500,000 | 500,000 |  | 12,762,816 |
| 6 |  | 500,000 | 500,000 |  | 13,400,956 |
| 7 |  | 500,000 | 500,000 |  | 14,071,004 |
| 8 |  | 500,000 | 500,000 |  | 14,774,554 |
| 9 |  | 500,000 | 500,000 |  | 15,513,282 |
| 10 | 10,000,000 | 500,000 | 10,500,000 | 16,288,946 | 16,288,946 |
|  | 10,000,000 | 5,000,000 | 15,000,000 | 16,288,946 |  |

## 4. Bond Redemptions and Accrued Interest

## Serial, Term Bonds and Sinking Fund Payments

## Oveniew

When bondsare initially sold by an issuerthey are sold with a coupon rate and are given a maturity date...the date when the bondsare scheduled to be paid off by the issuer of the bonds. There are two types of structures that these bondscan take.

## Serial Bonds

These bond are straightforward. They are structured as you would expect a bond to be structured: a known coupon rate and a specific maturity date. When you buy this bond you know what income you expect to receive until the maturity date when your original principal a mount will be retumed to you (assuming all goes well!).

## Bond Redemptions and Accrued Interest (continued)

## Term Bonds

These bondsdon't pay back the entire principalat maturity. Instead, a portion of the principal is paid before the final maturity. These payments are called "sinking fund payments." Bonds are sold asterm bond susually for convenience...it is ea sier to sell a term bond of $\$ 10,000,000$ with a final maturity date of $1 / 1 / 2015$, but with sinking fund payments from 2012 through 2014, than it is to sell four separate bonds with $\$ 2,500,000$ maturities from 2012 through 2015. La rge investors (like bond mutual funds) also like buying la rger maturities as they are more liquid and easier to trade. Here is what the structure looks like forthisterm bond:

| Payment <br> Date | Principal <br> Amount |
| :---: | :--- |
| $1 / 1 / 2012$ | $2,500,000$ Sinking Fund Payment |
| $1 / 1 / 2013$ | $2,500,000$ Sinking Fund Payment |
| $1 / 1 / 2014$ | $2,500,000$ Sinking Fund Payment |
| $1 / 1 / 2015$ | $2,500,000$ Final Maturity |
|  | $10,000,000$ |

## Bond Redemptions and Accrued Interest (continued)

## Term Bonds (continued)

The owner of a term bond is not sure exactly when the bond, or a portion of the bond, is going to be redeemed. The bondsthat are picked to be redeemed on a sinking fund payment date are usually chosen randomly and the owners are informed that a portion of their bond has been picked to be redeemed. In the previousexample a holder of a $\$ 1,000,000$ bond could have all, orsome, of the bond "called away" on J a nuary $1^{\text {t }}$ of 2012, 2013, or 2014 with any rema ining principal repaid on J anuary 1, 2015 (its final maturity date).

## Bond Redemptions and Accrued Interest (continued)

## Bond Redemptions and Accrued Interest

Bonds are either redeemed at maturity, on a regularly scheduled sinking fund payment date (for tem bonds), or on an optional call date. Money forthe payment is transferred from the issuer of the bonds to a "paying agent" who handles getting the money to the bond holder in exchange for the bond which isthen canceled. At the time the bond is redeemed interest on the bond is also due. This is the accrued interest that has accumulated since the last interest payment date on the bonds. Every day that passes interest "accrues" on a bond and is an obligation that the issuer of the bond hasto the owner of that bond.

[^0]
## 5. Spreadsheet Formulas

Spreadsheet programs have built in functionsforcalculating bond prices, bond yields, and otherfinancial values. In Excel these include:

$$
\begin{array}{ll}
=\text { Price }() & \text { Calculates the price of a bond } \\
=\text { Yield }() & \text { Calculates the yield on a bond } \\
=\operatorname{IRR}() & \begin{array}{l}
\text { Calculates the Internal Rate of Return } \\
\text { on a bond issue }
\end{array} \\
=\text { PMT() } & \begin{array}{l}
\text { Calculates the annual payments required } \\
\text { in order to pay off a bond issue }
\end{array}
\end{array}
$$

The next few pagescontain descriptions of these functionsand how they are used.

## =Price()

## Calculates the price of a bond (given the yield)

The price of a bond, at its most basic, is simply the present value of all the future payments to be received on that bond. The discount rate used to calculate that present value is the yield on the bond. The arguments that the function takes (separated by commas) are:

## $=$ Price(delivery date, maturity date, coupon, yield, value at maturity, number of coupon payments / year, day count basis)

```
delivery date
maturity date
coupon
yield
value at maturity
number of coupon
    payments/year
day count basis
```

The date the bond is paid for (also called the "settlement date").
The date the final principal payment is received on the bond.
The periodic interest received on the bonds ( $5 \%$ coupon on a $\$ 100$ bonds pays $\$ 5 /$ year).
The rate used to calculate the present value of the future payments to be received
The value of the bond at maturity (per $\$ 100$ face value). For municipal bonds you would usually just enter 100.
For municipal (and the majority of other) bonds you receive semi-annual payments so you enter 2.
Different kinds of bonds have different methods for counting the days between dates, whether it is the actual number of days or a simplified way assuming 30 day months. Municipal bonds use the 30 day month/360 day year convention so you enter 0 in this field (although you can leave it blank in which case Excel assumes it is 0).

## =Price() <br> Calculates the price of a bond (given the yield)

## Example Problem:

You are being asked if you are interested in buying a municipal bond. You are not told what the price of the bond is but you are told that the yield is $4.50 \%$, the coupon is $5.00 \%$, that the maturity date isJ a nuary $1^{\text {st, }}, 2030$ a nd the delivery date is September 19th, 2011. How can you use this information to calculate the price of the bond?

## =Price()

## (continued)

## Example Problem:

| 4 | A | B | C | D | E | F |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | =PRICE() |  |  |  |  |  |
| 2 |  |  |  |  |  |  |
| 3 | Formula: | =Price(B7,B8, | 9,B | 11, | B1 |  |
| 4 |  | - |  |  |  |  |
| 5 | Result: | 106.179 |  |  |  |  |
| 6 |  | 106.179 |  |  |  |  |
| 7 | Delivery (Settlement) Date: | 9/19/2011 |  |  |  |  |
| 8 | Maturity Date: | 1/1/2030 |  |  |  |  |
| 9 | Coupon: | 5.000\% |  |  |  |  |
| 10 | Yield: | 4.500\% |  |  |  |  |
| 11 | Value at Maturity: | 100 |  |  |  |  |
| 12 | \# of Coupon Payments/Year: | 2 |  |  |  |  |
| 13 | Day Count Basis: | 0 |  |  |  |  |
| 14 |  |  |  |  |  |  |

## =Yield()

## Calculates the yield on a bond (given the price)

The yield on a bond is the ea mings rate you receive if you purchase it. Technic ally, it is an Intemal Rate of Retum (IRR): the rate that, when used to present value all the future payments to be received from the bond equals its purchase price. The arguments that the function takes (separated by commas) are:

## =Yield (delivery date, maturity date, coupon, price, value at maturity, number of coupon payments/year, day count basis)

delivery date maturity date coupon
price
value at maturity
number of coupon payments/year day count basis

The date the bond is paid for (also called the "settlement date").
The date the final principal payment is received on the bond.
The periodic interest received on the bonds ( $5 \%$ coupon on a $\$ 100$ bonds pays $\$ 5 /$ year). The price paid for the bond.
The value of the bond at maturity (per $\$ 100$ face value). For municipal bonds you would usually just enter 100 .
For municipal (and the majority of other) bonds you receive semi-annual payments so you enter 2.
Different kinds of bonds have different methods for counting the days between dates, whether it is the actual number of days or a simplified way assuming 30 day months. Municipal bonds use the 30 day month/360 day year convention so you enter 0 in this field (although you can leave it blank in which case Excel assumes it is 0).

## =Yield()

## Calculates the yield on a bond (given the price)

## Example Problem:

This time when you are offered the municipal bond you are told the price but not the yield. You are told that the price of the bond is 106.179, the coupon is $5.00 \%$, the maturity date isJ a nuary $1^{\text {st }}, 2030$, and the delivery date is September 19th, 2011. How can you use this information to calculate the yield on the bond?

## =Yield()

## (continued)

## Example Problem:

|  | A | B | C | D | E | F |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | =YIELD() |  |  |  |  |  |
| 2 |  |  |  |  |  |  |
| 3 | Formula: | =Yield(B7, B8, | 9,B1 | 11, | B1 |  |
| 4 |  | - |  |  |  |  |
| 5 | Result: | 4.500\% |  |  |  |  |
| 6 |  | , |  |  |  |  |
| 7 | Delivery (Settlement) Date: | 9/19/2011 |  |  |  |  |
| 8 | Maturity Date: | 1/1/2030 |  |  |  |  |
| 9 | Coupon: | 5.000\% |  |  |  |  |
| 10 | Price: | 106.179 |  |  |  |  |

| 12 | \# of Coupon Payments/Year: | 2 |  |  |  |  |
| 13 | Day Count Basis: | 0 |  |  |  |  |
| 14 |  |  |  |  |  |  |

## $=(R R()$

Calculates the Intemal Rate of Retum/True Interest Cost of a bond issue

When a bond issue is sold it is made up of a number of separate bond maturities that are sold at one time. Just as we saw that the yield on a bond is the interest rate that equates the present value of all future payments to be received on a bond to its price, the IRR equates the present value of the payments to be made on $A \amalg$ the bond maturities issued to the NETprice received from the sale of all the separate bonds (net of the costs associated with issuing the bonds). In essence, the IRR is the overall interest rate on the bond issue and in the municipal bond world this is called the True Interest Cost (IIC).

## =IRR(values, guess)

values
guess

A series of amounts entered in the separate cells of the spreadsheet. There must be at least one negative and one positive value.
A yield that gives the IRR formula a place to start its calculations. If omitted Excel assumes $10 \%$ (0.10).

## $=(R R()$ <br> (continued)

## Example Problem:

As an example, we will assume a simple bond issue with just two separate maturities. In the spreadsheet, we enter the cash flowsto be paid on each bond sold, add up those payments by date paid, add up the total amount received from the sale of the bonds and then calculate the IRR.

Our simplified bond issue is sold on J a nuary $1^{\text {st }}, 2012$. The first bond matures on $1 / 1 / 2014$, has a coupon of $4.00 \%$, a yield of $4.25 \%$ (and therefore a price of 99.525 ), and a parvalue of $\$ 500,000$. The second maturity is on $1 / 1 / 2015$, has a coupon of $4.75 \%$, a yield of $4.50 \%$ (and therefore a price of 100.694 ), and a parvalue of $\$ 750,000$.

The costs associated with issuing the bonds(payments to la wyers, underwriters, and financial advisors) is $1.00 \%$ of the total parvalue. With this information we can calculate the overall True Interest Cost (IRR) of the bond issue.

## =PMT()

Calculates the annual payments required to pay off a bond issue

The payment function is a handy formula for estimating the annual payments required to pay off a bond issue. It is not as accurate as a complete debt service schedule which incomorates all of the details of the bonds that make up an entire bond issue but is does provide a rather quick, simple and accurate estimate of the annual payments required to pay off a bond issue of a given size with equal annual payments.

## $=P M T($ interest rate, years to maturity, bond issue size, 0,0 )

interest rate
years to maturity bond issue size

An estimate of the average interest rate of the bond issue.
How long the bond issue will be outstanding.
The total amount of bonds to be issued.

## =PMT()

Calculates the annual payments required to pay off a bond issue

## Example Problem:

Smallville is considering a proposal to build a new library that costs $\$ 10$ million. It wants to quickly make a general estimate of what the annual debt service would be on a bond issued to build the library.

We assume the bonds will have a 30 yearfinal maturity, the average bond rate will be $5.00 \%$ and the annual payments on the bonds will be level over the life of the bonds.

## = PMT() <br> (continued)

Example Problem:

| , | A | B | C | D |
| :---: | :---: | :---: | :---: | :---: |
| 1 | =PMT() |  |  |  |
| 2 |  |  |  |  |
| 3 | Formula: | $=-\mathrm{Pmt}(\mathrm{B} 7, \mathrm{~B} 8$, | ,0,0) |  |
| 4 |  | $\square$ |  |  |
| 5 | Result: | 650,514 |  |  |
| 6 |  | , |  |  |
| 7 | Interest Rate: | 5.000\% |  |  |
| 8 | Years to Maturity: | 30 |  |  |
| 9 | Bond Issue Size: | 10,000,000 |  |  |
