# Functions of the Cell Membrane

- Contains the cell
- Regulates the traffic of molecules and substances in and out of the cell (*semi-permeable membrane*)

# Cell Membrane Structure

***Pancreatic Secretory Cell: TEM of Basal and Apical Parts***

# Major Components of the Cell Membrane

- The major constituents of the cell membrane are proteins and lipids
- *Membrane proteins* and lipids are arranged in a particular fashion, both contributing to containing the cell and to selectively allowing or blocking the traffic of certain substances through the cell
- Such arrangement of molecules provides *fluidity* to the cell membrane

# Major Components of the Cell Membrane: Lipids

- Phospholipids are *amphipathic* molecules (with *hydrophobic* tails and a *hydrophilic* head)
- One of the phospholipid tails exist mostly in a *trans* configuration, providing *more fluidity* to the membrane
- Cholesterol is a rigid molecule that makes membranes *less fluid*

# Major Components of the Cell Membrane: Lipids

(a) Movement of phospholipids

(b) Membrane fluidity

(c) Cholesterol within the animal cell membrane

***One of the phospholipid tails exist mostly in a trans configuration, providing more fluidity to the membrane***

***Cholesterol is a rigid molecule that makes membranes less fluid***

# How Are Phospholipids Organized in the Cell Membrane?

- Phospholipids constitute two mirror-image oriented layers — *the lipid bilayer*
- The hydrophilic heads are exposed to the high-content water regions, while the hydrophobic tails constitute a barrier impenetrable to almost all substances

# hydrophobic tails: repel water: phospholipids: lipid bilayer

1. makes sense
2. makes no sense

# Major Components of the Cell Membrane: Membrane Proteins

- Membrane proteins are embedded in the fluid matrix of the lipid bilayer
- More than 50 types of proteins have been found in the plasma membrane. Membrane proteins determine most of the membrane specific functions
- Transport proteins, enzymes and receptor proteins (membrane proteins that interact with other cells or molecules) include the vast majority of membrane proteins

# Major Components of the Cell Membrane: Organization

# Major Components of the Cell Membrane: Organization

# Functions of the Cell Membrane

- Contains the cell
- Regulates the traffic of molecules and substances in and out of the cell (*semi-permeable membrane*)

# Traffic of Substances Across the Plasma Membrane

- Selective
- Bidirectional
- Depending Upon Differences of Concentration Inside and Outside of the Cell

# Traffic of Substances Across the Plasma Membrane

- **Selective:** only a few molecules can go through the lipid bilayer. Transport proteins mostly determine what substances cross the cell membrane, as they carry out the majority of membrane transport

# Traffic of Substances Across the Plasma Membrane

- **Bidirectional:** only a few molecules can go through the lipid bilayer. Transport proteins determine what substances cross the cell membrane. Transport can occur in/out or out/in

# Traffic of Substances Across the Plasma Membrane

- **Depending Upon Differences of Concentration Inside and Outside of the Cell:** *Osmosis* and *diffusion* are the two main processes by which molecules move across the cell membrane

# \_\_\_\_\_ control the traffic of molecules through the cell membrane

1. Membrane proteins
2. Lipids
3. Membrane proteins and lipids

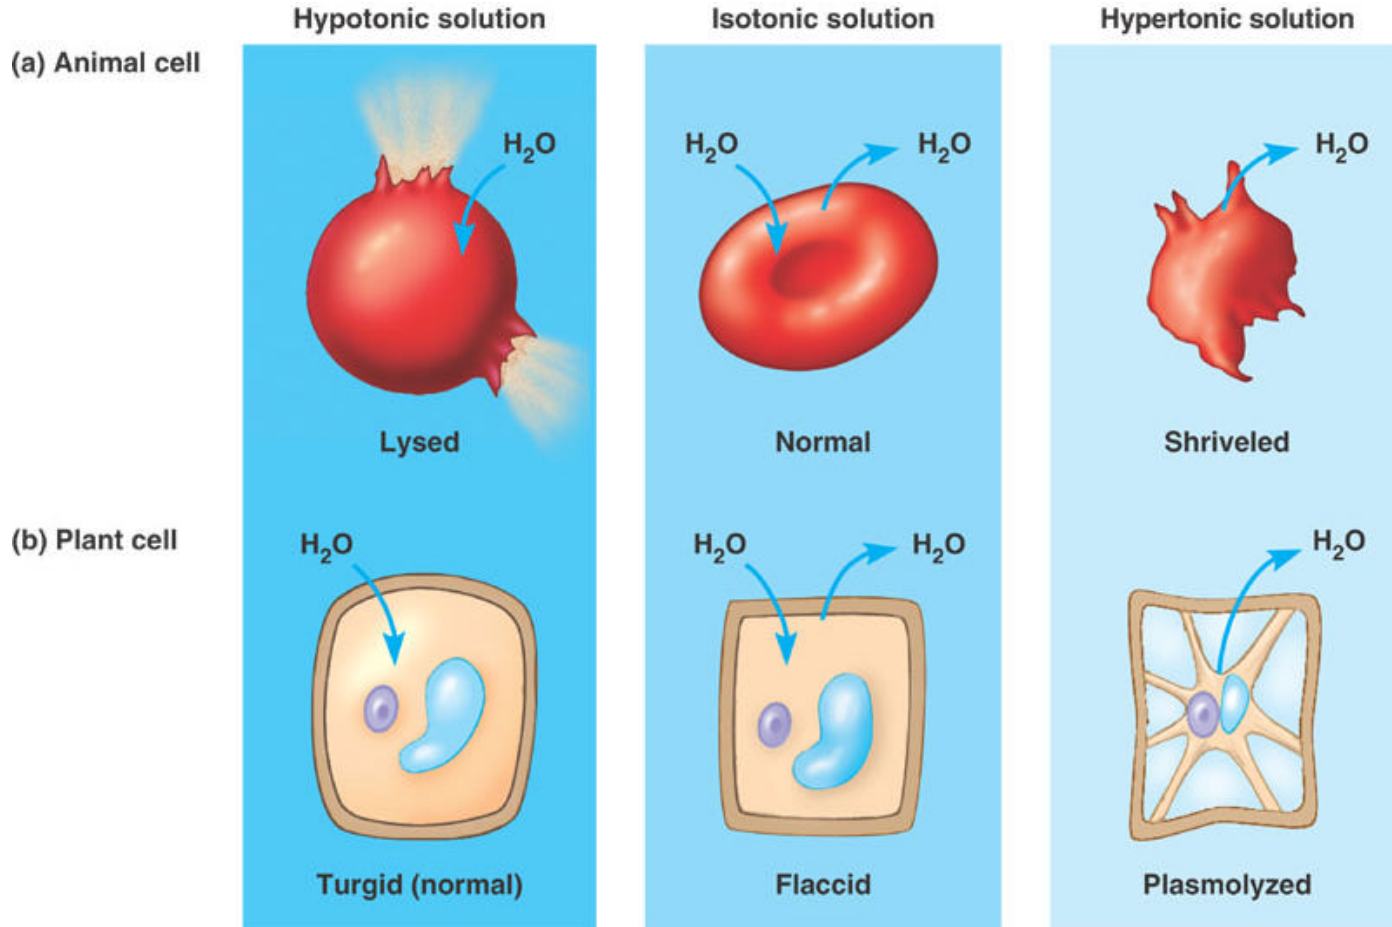

# Traffic of Substances Across the Plasma Membrane: Osmosis

- Osmosis is the movement of water and some small molecules *through a semi-permeable membrane* from areas of low concentration of solutes to areas of high concentration of solutes
- Why does water move in that particular direction?

# Traffic of Substances Across the Plasma Membrane: Osmotic Shock

# Traffic of Substances Across the Plasma Membrane: Osmosis

- Draw a situation where the extracellular environment is such that water flows out of the cell
- Is the extracellular environment hypo-, hyper-, or isotonic?

# In this situation, will water flow out of the cell?

Cartilage cells

1. Yes
2. No

# Traffic of Substances Across the Plasma Membrane: Diffusion

- Diffusion is the movement of substances from an area of high concentration of solutes to an area of low solute concentration (*down to a concentration gradient*)

# Traffic of Substances Across the Plasma Membrane: Diffusion

- Draw a situation where a molecule of NaCl will enter the cell. Assume that a transport protein is needed
- Is the extracellular environment hypo-, hyper-, or isotonic?
- Direction of water?

# In this situation, will a molecule of NaCl enter the cell?

Cartilage cells

1. Yes
2. No

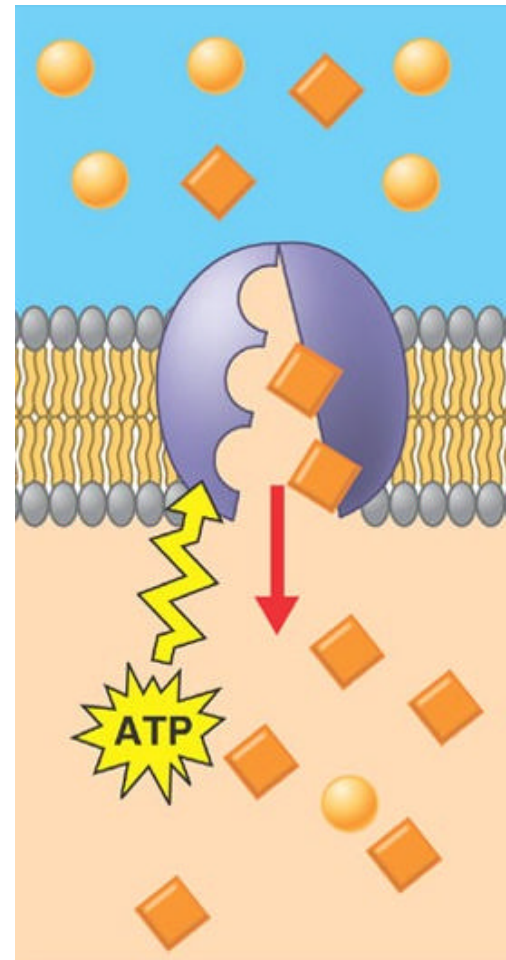

# Traffic of Substances Across the Plasma Membrane: Facilitated Diffusion

- Facilitated diffusion is a *protein-mediated passive* (no energy required) diffusion of molecules across the cell membrane
- Transport proteins carry out facilitated diffusion; facilitated diffusion is very selective, as each transport protein transports just one type of molecule

# Traffic of Substances Across the Plasma Membrane: Active Transport

- Active transport is a *protein-mediated* transport of molecules across the cell membrane *against a concentration gradient* (low to high solute concentration areas). It requires a boost of energy (ATP) to occur. As facilitated diffusion, is very selective
- Glucose is actively transported through the plasma membrane of intestinal cells

# Bulk Transport of Substances Across the Plasma Membrane: Exocytosis and Endocytosis

**Pancreatic Secretory Cell: TEM**

# Types of Endocytosis: Phagocytosis

*In phagocytosis ("cell eating"), a cell engulfs a particle or another cell through the emission of pseudopodia, and packs it into a vacuole. The contents of the vacuole is digested after the vacuole fuses with a lysosome*

*Phagocytosis of erythrocytes (Er) by blood macrophages (Ma).*

# Types of Endocytosis: Pinocytosis

- In pinocytosis (“cell drinking”), the cell takes in droplets of extracellular fluid into small vesicles. Many molecules enter the cell dissolved in the droplets in a non-specific manner

# Types of Endocytosis: Receptor-Mediated Endocytosis

- Receptor-mediated endocytosis requires of specific receptor proteins located in the cell membrane. Cell receptors interact with the molecule to be transported into the cell through a *ligand* — a molecule that binds specifically to the receptor
- Receptor-mediated endocytosis is highly specific. Human cells use receptor-mediated endocytosis to take in cholesterol. Some viruses (i.e. HIV virus) enters the cell through receptor-mediated endocytosis
- Mutations in receptor proteins involved in receptor-mediated endocytosis usually block the entrance of substances meant to be transported by this process (i.e. natural HIV immunity, familial hypercholesterolemia)

# The arrows point to a process of:

1. receptor-mediated endocytosis
2. exocytosis
3. phagocytosis

# The arrows point to a process of:

1. receptor-mediated endocytosis
