

Protein Synthesis

Protein Synthesis

How Genes Become Constituent Molecules

Mendel and The Idea of Gene

Gregor Mendel

What is a Chromosome?

A chromosome is a molecule of DNA

1. True
2. False

Protein Synthesis

How Genes Become Constituent Molecules

Protein Synthesis: What Is It?

- All proteins are synthesized according to instructions contained in the DNA nucleotide sequence, which is unique to every individual
- Protein synthesis is a two step process that consists of *transcription* and *translation*.

(a) Prokaryotic cell

(b) Eukaryotic cell

Protein Synthesis: What Is It?

- During transcription a molecule of messenger RNA (mRNA) is synthesized according to instructions provided by the DNA
- During translation, a polypeptide chain will be produced according to instructions provided by the mRNA

(a) Prokaryotic cell

(b) Eukaryotic cell

Protein Synthesis in Prokaryotes

- In prokaryotes, transcription and translation occur in the same cellular compartment — the cytosol. Ribosomes are the site of translation

(a) Prokaryotic cell

Protein Synthesis in Eukaryotes

- In eukaryotes, mRNA is synthesized in the nucleus from pre-messenger RNA (pre-mRNA) molecules, and then shipped to the cytoplasm, where translation occurs
- RNA processing (or *post-transcriptional modification*) refers to the molecular mechanisms that lead to the production of mRNA from pre-mRNA.

(b) Eukaryotic cell

The main difference between protein synthesis in eukaryotes and in prokaryotes is:

1. where the process happens
2. what the process produces
3. the participants in the process

Protein Synthesis: From Gene to Protein

- Genes are stretches of nucleotides organized in *triplets*
- Different arrangements or DNA triplets encode for each one of the 20 amino acids that make proteins
- During transcription, a DNA triplet will produce an mRNA *codon*.
- During translation, a codon will constitute an amino acid

Protein Synthesis: From Gene to Protein

		Second mRNA base					
		U	C	A	G		
U	UUU	Phe	UCU	UAU	UGU	Tyr	Cys
	UUC						
	UUA	Leu	UCA	UAA	UGA	Stop	Stop
	UUG						
C	CUU	Leu	CCU	CAU	CGU	His	Arg
	CUC						
	CUA	Pro	CCA	CAA	CGA	Gln	Arg
	CUG						
A	AUU	Ile	ACU	AAU	AGU	Asn	Ser
	AUC						
	AUA	Thr	ACA	AAA	AGA	Lys	Arg
	AUG						
G	GUU	Val	GCU	GAU	GGU	Asp	Gly
	GUC						
	GUA	Ala	GCA	GAA	GGA	Glu	Gly
	GUG						

First mRNA base (5' end)

Third mRNA base (3' end)

Transcription: What Is It Transcribed?

- RNA polymerase binds to the gene's promoter region and starts making a molecule of mRNA until it finds a “mark” in the gene or *termination sequence*.
- The term *transcription unit* refers to the segment of DNA between the sites of initiation and termination of transcription by RNA polymerase. More than one gene may reside in a transcription unit.

Transcription: Initiation

Nascent mRNA: RNA transcript

Transcription: Elongation

Transcription: Elongation

- RNA is synthesized according to DNA/RNA base pairing rules:

A (DNA) — **U** (RNA)

G (DNA) — **C** (RNA)

T (DNA) — **A** (RNA)

C (DNA) — **G** (RNA)

The Making of an mRNA

DNA

5' ATTGCGTAGTG GGGATTAT 3'

RNA

Transcription: Termination

RNA polymerase : RNA transcript : unwound DNA

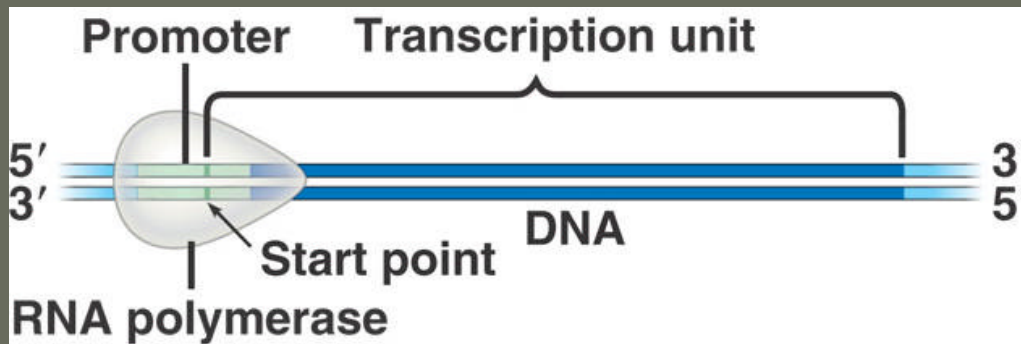

1. translation's initiation
2. translation's elongation
3. translation's termination

translation's initiation

translation's elongation

translation's termination

RNA polymerase : promoter : transcription unit

1. translation's initiation
2. translation's elongation
3. translation's termination

translation's initiation

translation's elongation

translation's termination

This cartoon illustrates:

1. translation's initiation
2. translation's elongation
3. translation's termination

Transcription: Eukaryotic Promoters

- In eukaryotes, promoters are activated by DNA binding proteins or *transcription factors*
- TATA boxes are segments of about 30 base pairs to which RNA polymerase binds

Transcription in Eukaryotes: Splicing of pre-mRNA Molecules

- Eukaryotic transcripts (pre-mRNA) contains *exons* (coding sequences) and *introns* (non coding sequences)
- Post-transcriptional modifications (i.e. splicing) remove introns before shipping the final mRNA to the cytoplasm

Transcription in Eukaryotes: Splicing of pre-mRNA Molecules

- Spliceosomes are organelles in which the excision and splicing reactions that remove introns from pre-mRNA occur
- Ribozymes and small nuclear RNAs (snRNA) are contained in spliceosomes

Transcription in Eukaryotes: Splicing of pre-mRNA Molecules

Introns are not translated.

1. True
2. False

Splicing only occurs in eukaryotes.

1. True
2. False

Translation: Production of Polypeptide Chains

Translation: transfer RNA (tRNA)

- Every transfer RNA (tRNA) has a specific sequence of nucleotides, complementary to an mRNA codon — the *anticodon*.
- Opposite to the anticodon, there is an attachment site specific for each of the 20 amino acids.

(a) Two-dimensional structure

Translation: transfer RNA (tRNA)

Translation: mRNA/tRNA Interaction

- The recognition of codon (mRNA) and anticodon (tRNA) occurs in the ribosomes.
- Ribosomes have sites of tRNA anchorage and exiting
- A growing polypeptide will be produced following instructions in the mRNA

(a) Computer model of functioning ribosome

(b) Schematic model showing binding sites

(c) Schematic model with mRNA and tRNA

Translation: Initiation and Elongation of the Polypeptide Chain

- A start codon (AUG) complements with the Methionine (Met) tRNA in the ribosome, constituting the *translation initiation complex*
- A new anticodon will land in the A site, and its amino acid will join Met. The tRNA will slide to the P site leaving the A site free for another anticodon

Translation: Initiation and Elongation of the Polypeptide Chain

Translation: Termination

- A stop codon (UAG, UAA, or UGA) signals the end of the mRNA molecule. A release factor triggers the disassembling of the two ribosomal units and the mRNA molecule.

uracil : codon : transcription

1. mRNA
2. pre- mRNA
3. tRNA
4. DNA

uracil : anticodon : translation

1. mRNA
2. pre- mRNA
3. tRNA
4. DNA

thymine : triplet : genetic message

1. mRNA
2. pre- mRNA
3. tRNA
4. DNA

Polyribosomes

- An mRNA molecule is generally translated simultaneously by several ribosomes that constitute *polyribosomes*

(a) An mRNA molecule is generally translated simultaneously by several ribosomes in clusters called polyribosomes.

(b) This micrograph shows a large polyribosome in a prokaryotic cell (TEM).
